Executive Summary

The Puget Sound Clean Air Agency (the Agency) summarizes air quality data from our core monitoring network every year. This report summarizes regional air quality by presenting air quality monitoring results for six criteria air pollutants and air toxics. The U.S. Environmental Protection Agency (EPA) sets national ambient air quality standards (NAAQS) for the criteria pollutants. The criteria pollutants are:

- Particulate Matter (particles 10 micrometers and smaller [PM₁₀] and 2.5 micrometers and smaller in diameter [PM_{2.5}])
- Ozone
- Nitrogen Dioxide
- Carbon Monoxide
- Sulfur Dioxide
- Lead

Air toxics are defined by Washington State and the Agency to include hundreds of chemicals and compounds that are associated with a broad range of adverse health effects, including cancer.¹ Many air toxics are a component of either particulate matter or volatile organic compounds (a precursor to ozone). The Air Quality Index (AQI)² is a nationwide reporting standard for the criteria pollutants. The AQI is used to relate air quality levels to health effects in a simplified way and is intended mainly for forecasting and real-time communication. “Good” AQI days continued to be in the majority 2023. However, air quality degraded into “moderate” for over 100 days in King and Snohomish Counties, and “unhealthy for sensitive groups” and “unhealthy” for a few days. There were no “very unhealthy” or “hazardous” days in King, Kitsap, Pierce, or Snohomish County in 2023.

The Agency and the Washington State Department of Ecology (Ecology) work together to monitor air quality within the Puget Sound region. The Agency’s jurisdiction includes King, Kitsap, Pierce, and Snohomish Counties. Real-time air monitoring data are available for pollutants at www.pscleanair.gov/157/Request-Air-Quality-Data.

To receive the Agency’s most updated news and stay current on air quality issues in King, Kitsap, Pierce and Snohomish counties, visit www.pscleanair.gov/258/Connect-With-Us and select your favorite news feed method. Friends and subscribers receive the latest on air quality news and updates on projects in the Puget Sound region. You can also find us on Facebook and Twitter.

Data included in this report are for our core monitoring network. We also perform local, seasonal monitoring studies – you can see reports on these study results at the library on our website at www.pscleanair.gov.

¹Washington Administrative Code 173-460. See Table of Toxic Air Pollutants, WAC 173-460-150.

apps.leg.wa.gov/WAC/default.aspx?cite=173-460-150

² <https://www.airnow.gov/aqi/aqi-basics/>

Over the last two decades, many pollutant levels have declined, and air quality has improved overall. In 2023, the overall air quality remained good, continuing the trend of improvement, though we still face challenges due to wildfire smoke. Elevated fine particle levels (PM_{2.5}) pose the greatest air quality challenge in our jurisdiction. The U.S. Environmental Protection Agency's (EPA's) health-based standard of 35 micrograms per cubic meter was exceeded 5 times in 2023, all of which were wildfire smoke influenced days or July 4th fireworks. With wildfire smoke removed, the Agency's more stringent local PM_{2.5} health goal of 25 micrograms per cubic meter over a 3-year average has been met in 2023, although Snohomish and Pierce Counties are very close to that level this year. Additionally, levels exceeded 25 micrograms per cubic meter on 15 days, 7 of which were due to wildfire smoke.

Ozone levels remain a concern in our region, however it has shown improvement as values have reduced at various sites. In 2023, all sites except for Enumclaw met the U.S. Environmental Protection Agency's (EPA's) revised 2015 standard of 0.070. Enumclaw had a 3-year design value of 0.073 ppm when including days with wildfire smoke present.

Some air toxics were measured at levels known to cause adverse health effects. These health effects include, but are not limited to, increased cancer risk, respiratory effects, and developmental effects.

Overall, the air quality in Puget Sound region has continued meeting the EPA standards. However, in August 2023, we had various wildfires impacting the air quality at our monitoring sites for six days. There were no very unhealthy or hazardous days in 2023. There were 3 unhealthy days and 3 unhealthy for sensitive group days, all of which were due to wildfire smoke or July 4th fireworks.

Monitoring Network

The Puget Sound Clean Air Agency (the Agency) and the Washington State Department of Ecology (Ecology) operated the monitoring network within the Agency's jurisdiction of King, Kitsap, Pierce, and Snohomish Counties in 2023. The network is comprised of meteorological and pollutant-specific monitors, as well as instruments dedicated to special studies. Data from the network are normally collected automatically via Ecology's data network, or in some cases, collected manually by field staff. Monitoring stations are located in a variety of geographic locations in the Puget Sound region. Monitors are sited according to EPA criteria to ensure a consistent and representative picture of air quality.

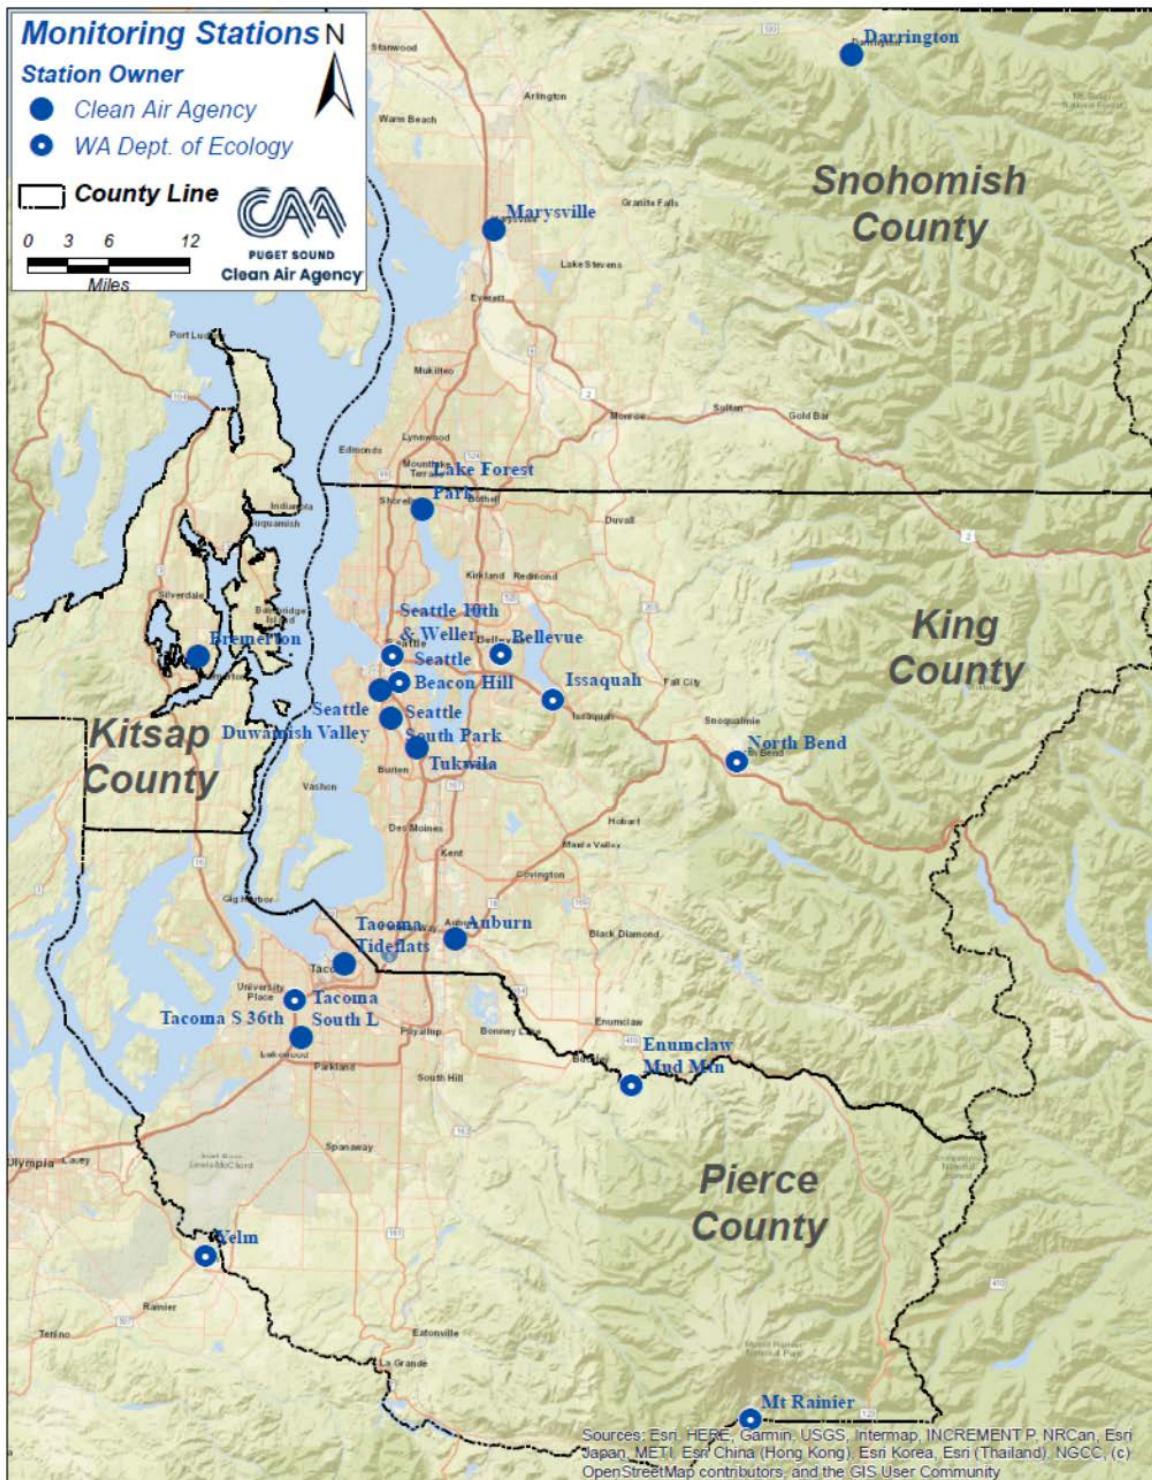

Map 1 and Table 1 show King, Kitsap, Pierce, and Snohomish County monitoring sites used in 2023. An interactive map is available at www.pscleanair.gov/NetworkMap. The Kent site (James St & Central Ave, Kent) was temporarily decommissioned 6/20/2023 and not shown on this map.

Page A-3 of the Appendix shows a list of the methods used for monitoring the criteria pollutants. Additional information on these methods is available at EPA's website at epa.gov/ttn/amtic/. Information on air toxics monitoring methods is available at epa.gov/ttn/amtic/airtox.html.

The Agency has been conducting air quality monitoring as early as 1965. A summary of the monitoring stations and parameters used over the history of the program is on page A-4 of the Appendix. The network changes periodically because the Agency and Ecology regularly re-evaluate monitoring objectives, resources, and logistics. You can also find a list of historical data summaries going back to 1972 here: <http://dl.pscleanair.org/Datasummaries/>.

Air Quality Index

EPA established the air quality index (AQI) as a simplified tool for communicating daily air quality forecasts and near real-time information. It is intended to help people plan their daily activities. The AQI indicates how clean or polluted air is and what associated health effects might be a concern. It focuses on health effects that may be experienced within a few hours or days after breathing polluted air. EPA calculates the AQI for five major air pollutants regulated by the Clean Air Act: ground-level ozone, particle pollution (also known as particulate matter or PM), carbon monoxide, sulfur dioxide, and nitrogen dioxide.

EPA mainly developed the AQI as a daily indicator or forecast of air quality. To view the real-time AQI for your area, visit <http://www.airnow.gov>. For more information about local air quality, visit www.pscleanair.gov/27/Air-Quality.

A higher AQI indicates higher levels of air pollution and greater health concern. An AQI value of 100 generally corresponds to the national air quality standard for the pollutant, which is the level EPA has set to protect public health. It's important to note that health effects can be experienced even at "good" or "moderate" levels.

The purpose of the AQI is to help people understand what local air quality means to health. To make it easier to understand, the AQI is divided into six categories:

Air Quality Index (AQI) Values	Levels of Health Concern	Colors
When the AQI is:	...air quality condition is:	...look for this color:
0 – 50	Good	Green
51 – 100	Moderate	Yellow
101 – 150	Unhealthy for Sensitive Groups	Orange
151 – 200	Unhealthy	Red
201 – 300	Very Unhealthy	Purple
301 – 500	Hazardous	Maroon

Table 1Table 2 shows the percentage of days in each AQI category by county for 2023. The maximum AQI value from all of our network monitors in a county determines its AQI category for the day. Most days were in the "Good" air quality category with many "Moderate" days, three "Unhealthy for Sensitive Groups" days, three "Unhealthy" days, and zero "Very Unhealthy" or "Hazardous" days. In

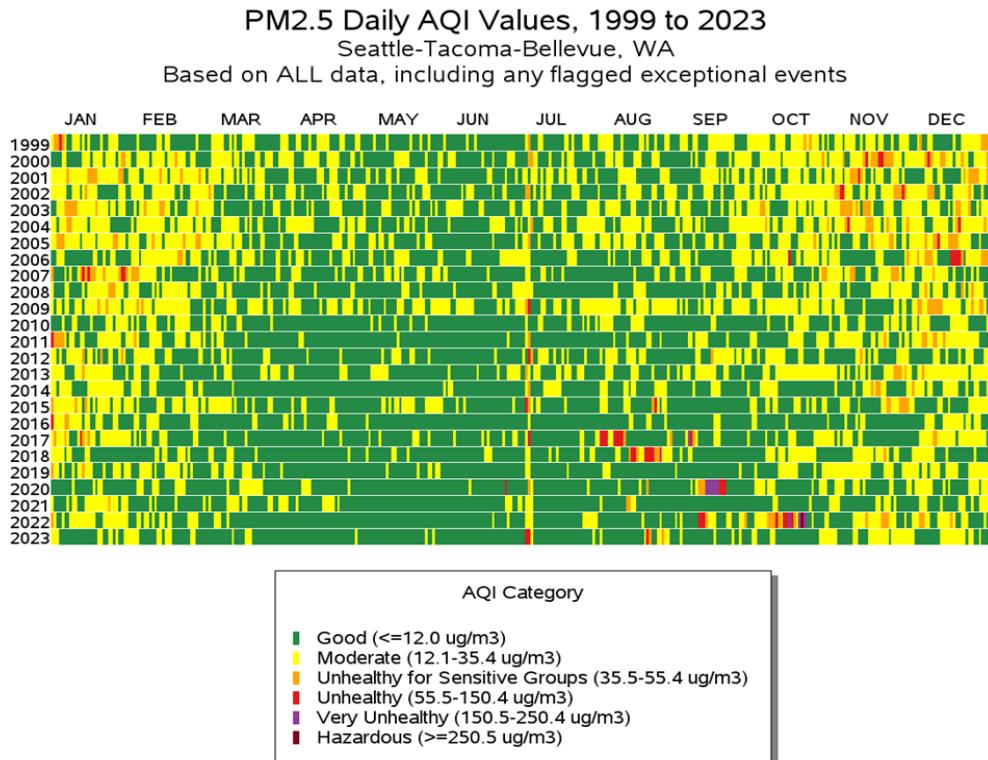

2023, the AQI ranges were made more conservative, meaning that we now have more days categorized as MODERATE than in previous years. This percentage cannot be compared directly to prior data summaries without using actual concentrations.

Table 2: Air Quality Index (AQI) Ratings for 2023

County	AQI Rating (% of year)					Highest AQI
	Good	Moderate	Unhealthy for Sensitive Groups	Unhealthy	Very Unhealthy	
King	59.2%	39.5%	1.1%	0.3%	0.0%	155
Kitsap	92.0%	7.7%	0.3%	0.0%	0.0%	115
Pierce	74.5%	24.7%	0.0%	0.8%	0.0%	195
Snohomish	67.0%	32.1%	0.5%	0.3%	0.0%	175

Figure 1 shows PM_{2.5} Daily AQI Values for Seattle-Tacoma-Bellevue, WA from 1999-2023. The figure shows trends over time and generally better air quality (more green days) in more recent years. This figure was produced by the [EPA Air Data Website](#). The figure also shows higher pollution days in the summer months due to wildfire smoke events.

Figure 1: PM_{2.5} Daily AQI Values for Seattle-Tacoma-Bellevue, WA from 1999-2023.

Particulate Matter

"Particulate matter," also known as particle pollution or PM, is a complex mixture of extremely small particles and liquid droplets. Particle pollution consists of several components, including acids (such as nitrates and sulfates), organic chemicals, metals, and soil or dust particles. PM can be categorized into three broad classes based on size: Coarse—with a diameter of 10 μm or less (PM_{10}); Fine—with a diameter of 2.5 μm or less ($\text{PM}_{2.5}$) and Ultrafine—with a diameter of less than 0.1 μm (UFP).

PM₁₀

PM_{10} is particulate matter with a diameter of 10 micrometers (or microns) or less. These particles can include larger particles like dust, and smaller particles ($\text{PM}_{2.5}$) that come mainly from combustion sources. Studies show that the finer $\text{PM}_{2.5}$ particles have more significant health risks. With levels well below the federal standard for years, the Agency ceased direct PM_{10} monitoring in 2006. For a historic look at the PM_{10} levels in the Puget Sound Region, please request a copy of the 2007 data summary, pages 32–35.³

PM_{2.5} Health and Environmental Effects

$\text{PM}_{2.5}$ (or fine particulate matter) has a diameter of 2.5 microns or less. An extensive body of scientific evidence shows that exposure to particle pollution is linked to a variety of significant health problems, such as increased hospital admissions and emergency department visits for cardiovascular and respiratory problems, heart attacks and premature death. Older adults, children, pregnant women, and those with pre-existing health conditions are more at risk from exposure to particle pollution. Particle pollution also reduces visibility in cities and some of our nation's most treasured national parks.

Fine particles are emitted directly from a variety of sources, including wood burning (both outside, and in wood stoves and fireplaces), vehicles and industry. They also form when gases from some of these same sources react in the atmosphere.

Ultrafine Particulate Matter (UFP)

Emerging health studies indicate that very tiny ultrafine particles with a diameter of 0.1 micron and less may be linked with negative health effects. Currently, there are no health-based standards on what a healthy level of ultrafine particles is. We are exploring new methods for measuring and assessing ultrafine particles, but this technology is not yet ready to add to our core monitoring network.

³ To request a document, please visit www.pscleanair.gov/272/2396/Records-Request

PM_{2.5}: Federal Reference Method and Continuous Methods

Fine particulate matter (PM_{2.5}) is measured using a variety of methods to ensure quality and consistency. EPA has defined a filter-based method as the federal reference method (FRM)—the primary method used to determine PM_{2.5} concentrations. EPA further defined several federal equivalent methods (FEM), which are continuous instruments operated under specific standard operating procedures. The main advantage of continuous FEMs is to provide PM concentrations at a higher temporal resolution (hourly averages) compared to the FRM (24-hour averages).

The Agency uses the FRM, FEMs, and a nephelometer estimation method to provide data. These methods determine fine particulate matter concentrations differently:

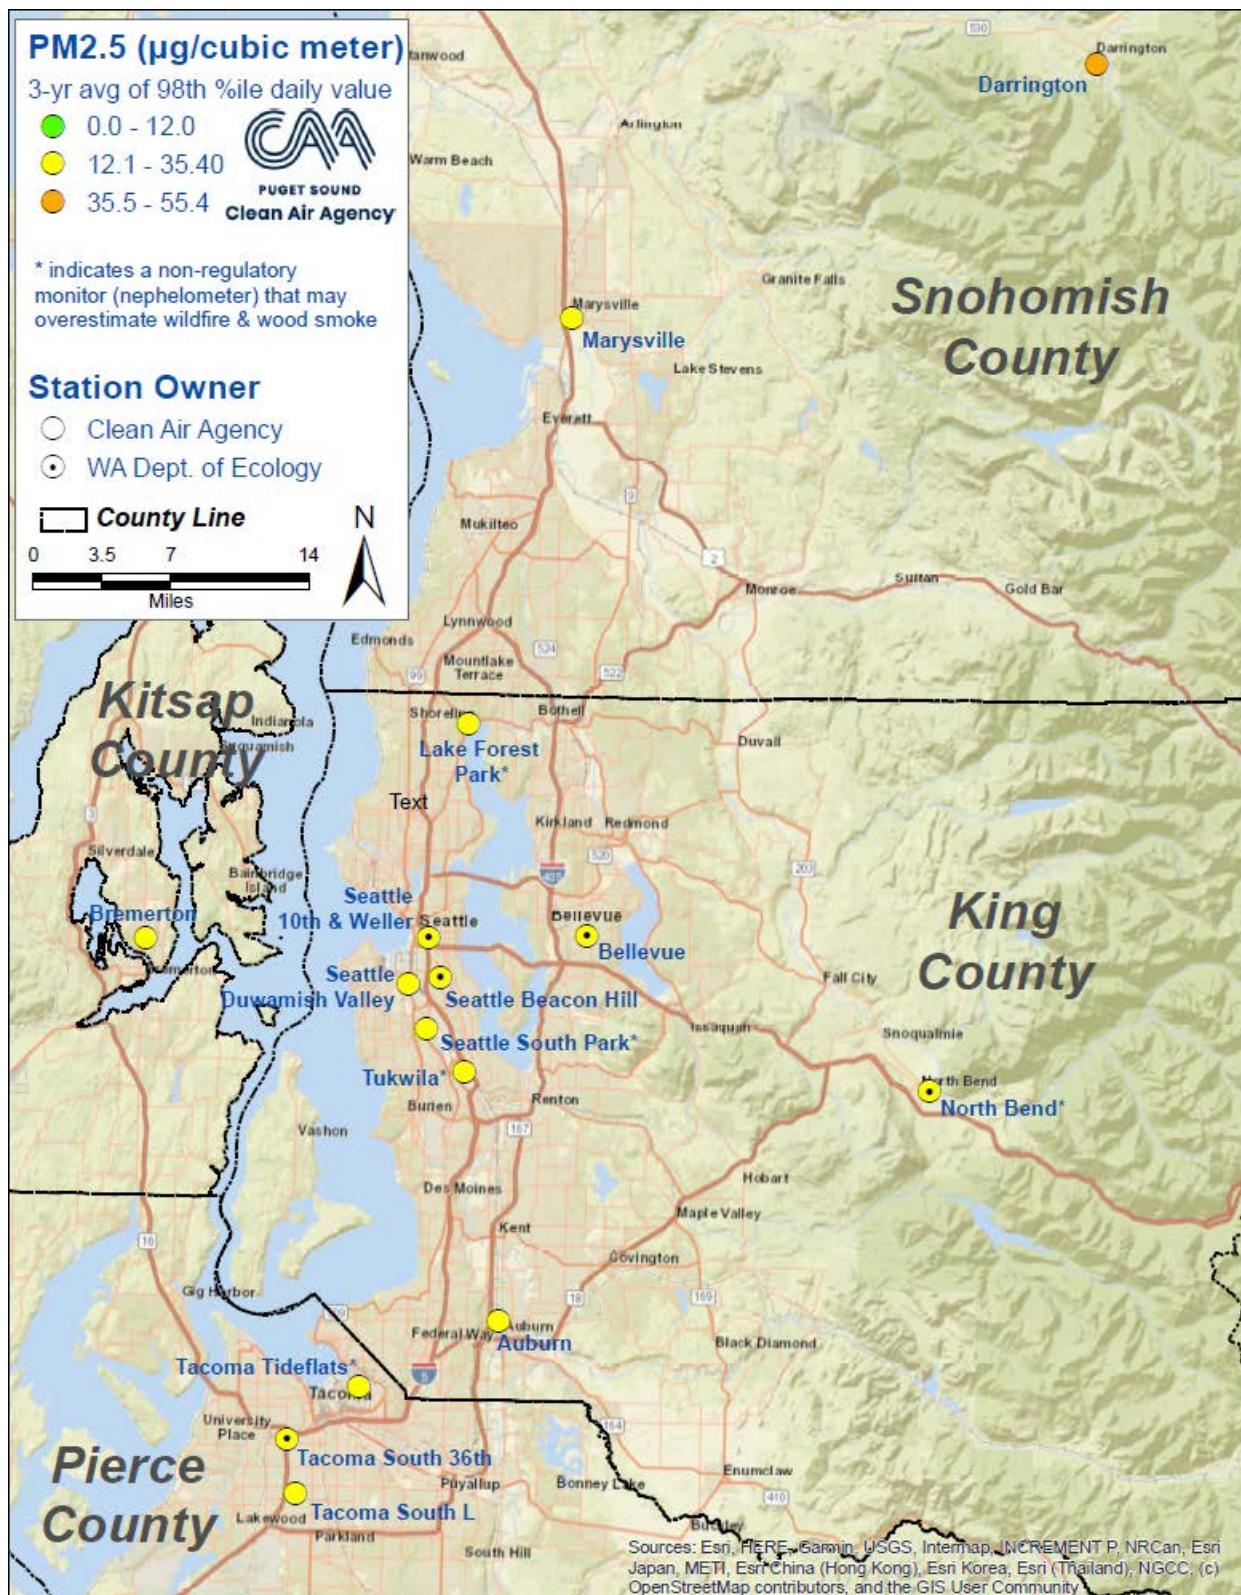

- The FRM involves pulling in air (at a given flow rate) for a 24-hour period and collecting particles with a diameter of 2.5 microns or smaller on a filter. The filter is weighed, and the mass is divided by air volume (determined from flow rate and amount of time) to provide concentration. Particles on the filter can later be analyzed for more information about the types of particulate matter.
- We operate a FEM instrument used in the network: the Met-One BAM, a beta attenuation monitor which uses the attenuation of beta radiation to assess the PM_{2.5} mass on a filter tape.
- The nephelometer measures the scattering of light in a photomultiplier tube; its results are then compared to FRM and FEM method data to produce an estimate of PM_{2.5}. While light scattering has been proven to correlate well with direct PM_{2.5} measurements, this is an “unofficial” method because it does not measure particle mass directly.

The Agency and Ecology work together on quality assurance to ensure the FEM-generated data are directly comparable to those generated by the reference method.

PM_{2.5} Daily Federal Standard

The EPA set a daily health-based fine particle standard of 35 micrograms per cubic meter ($\mu\text{g}/\text{m}^3$). Monitors in King, Kitsap, Pierce, and Snohomish Counties exceeded 35 $\mu\text{g}/\text{m}^3$ 5 days in 2023, all of which were due to wildfire smoke. In addition to the federal standard, our Board of Directors adopted a more stringent health goal of 25 $\mu\text{g}/\text{m}^3$. With wildfire smoke removed, the Agency's more stringent local PM2.5 health goal of 25 micrograms per cubic meter over a 3-year average has been met in 2023, although Snohomish and Pierce Counties are very close to that level this year. Additionally, levels exceeded 25 micrograms per cubic meter on 15 days, 7 of which were due to wildfire smoke. The majority of the remaining exceedance days were in November and December.

Map 2 shows the 98th percentile of the 3-year average of daily PM_{2.5} concentrations from 2021 to 2023 (with wildfire smoke included). This map incorporates data collected from federal reference, federal equivalent, and nephelometer estimation methods. The map also does not show sites with less than three years or incomplete data.

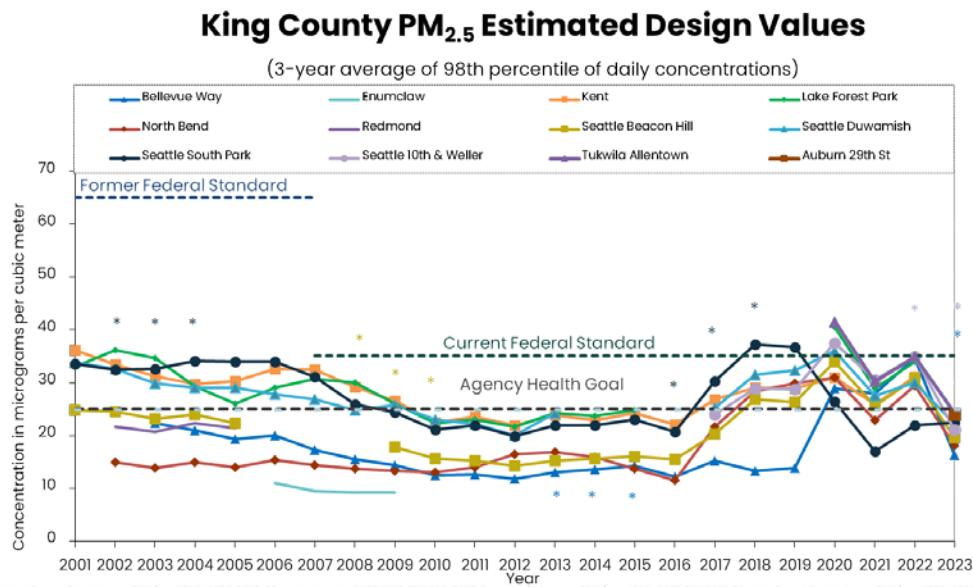

Map 2: The 98th Percentile 3-Year Average Daily PM_{2.5} Concentrations for 2023

Figures 2 through 9 show daily 98th percentile 3-year averages at each monitoring station in King, Kitsap, Pierce, and Snohomish Counties compared to the current daily federal standard. Points on the graphs represent averages for three consecutive years. For example, the value for 2023 is the average of the 98th percentile daily concentration for 2021, 2022, and 2023. These figures incorporate data collected from federal reference, federal equivalent, and nephelometer estimation methods. Due to Covid-19, federal reference monitoring could not be conducted from mid-March to July 2020, hence for these months only federal equivalent and nephelometer monitoring data has been used.

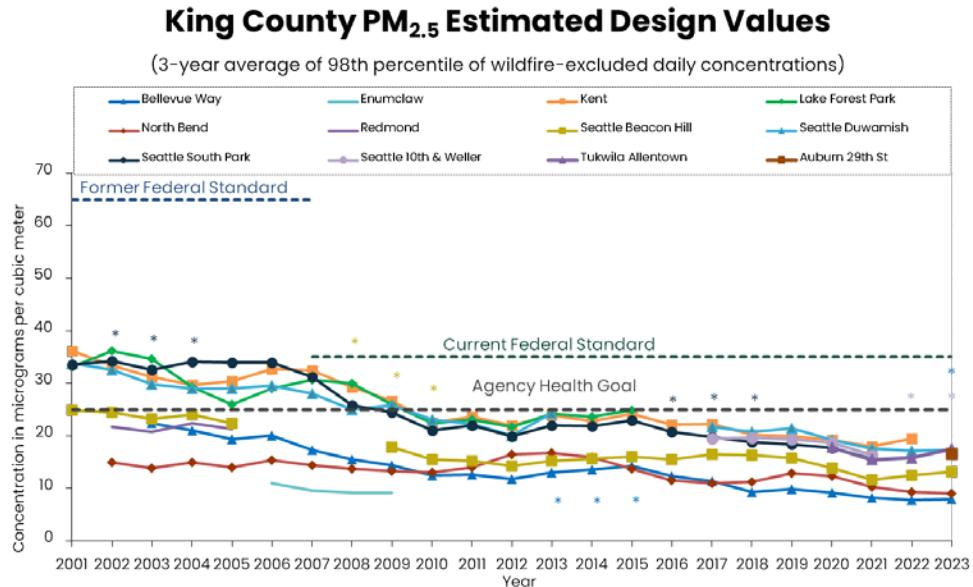

For each county, we include two figures: the first shows the entire dataset, and the second shows levels with wildfire smoke-impacted days removed in 2017, 2018, 2020, 2021, 2022, and 2023. The EPA allows data from days that were influenced by exceptional events that are beyond the ability of air agencies to control, such as wildfires or dust storms, to be excluded from regulatory calculations. There were 5 wildfire-impacted days in August 2023.

Figures 4 and 5 do not show any 2012–2014 data for Kitsap County because the Bremerton monitoring site moved to a new location and design values could not be computed until three complete years of data were collected at the new site. Statistical summaries for 98th percentile daily concentrations for 2023 data are provided on pages A-11 through A-13 of the Appendix.

Figure 2: Daily PM_{2.5} Design Values for King County

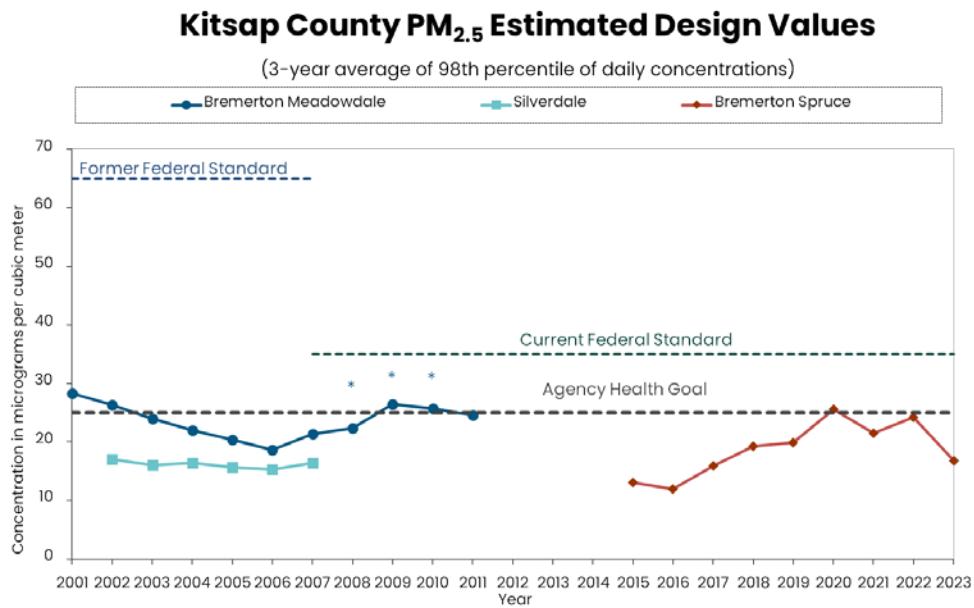

Note: Duwamish data are FRM from 1999–2005, 2007–09, nephelometer 2006, 2010, FEM 2011–2020. Beacon Hill data are FRM from 1999–2009, FEM 2010–20. Lake Forest Park data are FRM from 1999–2007, nephelometer in 2008–2020. South Park data are FRM from 1999–2004, nephelometer in 2005–2020. Bellevue Way data are FRM from 2001–2004, nephelometer 2005–20. Redmond data are FRM from 2000–2002, nephelometer from 2003–2005. Queen Anne data are nephelometer from 2002–2015. Olive Way data are nephelometer from 2003–2013. North Bend data are FRM from 2000–2004, nephelometer in 2005–2020. Kent data are FRM from 1999–2004, nephelometer in 2005–2010, FEM 2011–2020. Enumclaw data are from nephelometer in 2000–2009.

* Indicates an estimate based on incomplete data. Data less than 75% in a quarter at South Park in 2002 & 2016, Beacon Hill in 2008, Bellevue way in 2013, Seattle 10th and Weller in 2022, Bellevue in 2023.

 Figure 3: Daily PM_{2.5} Design Values for King County with wildfire-impacted days removed

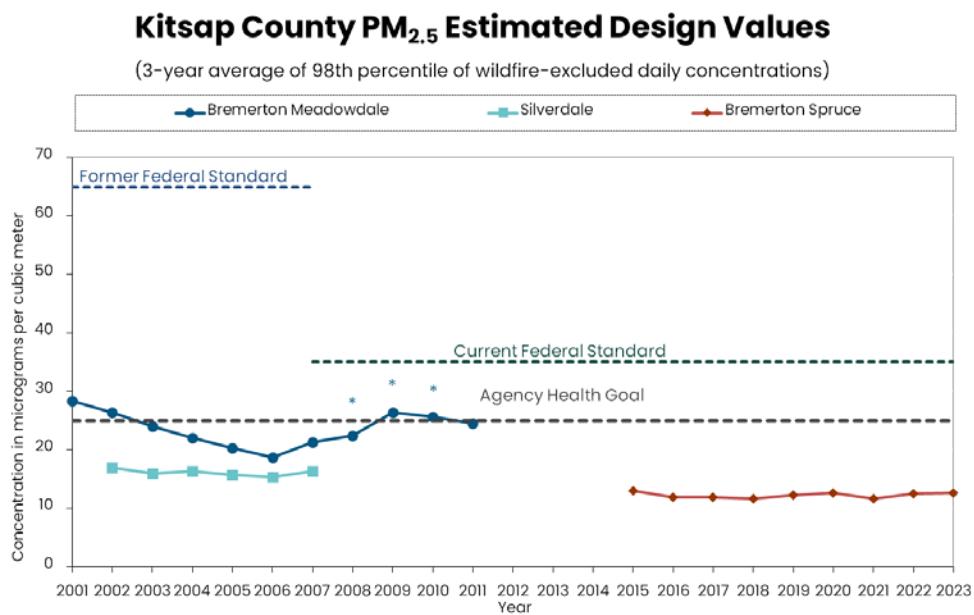

Note: Duwamish data are FRM from 1999–2005, 2007–09, nephelometer 2006, 2010, FEM 2011–2020. Beacon Hill data are FRM from 1999–2009, FEM 2010–20. Lake Forest Park data are FRM from 1999–2007, nephelometer in 2008–2020. South Park data are FRM from 1999–2004, nephelometer in 2005–2020. Figure 9: Daily PM_{2.5} Design Values for Snohomish County with wildfire-impacted days removed

PM_{2.5} Annual Federal Standard

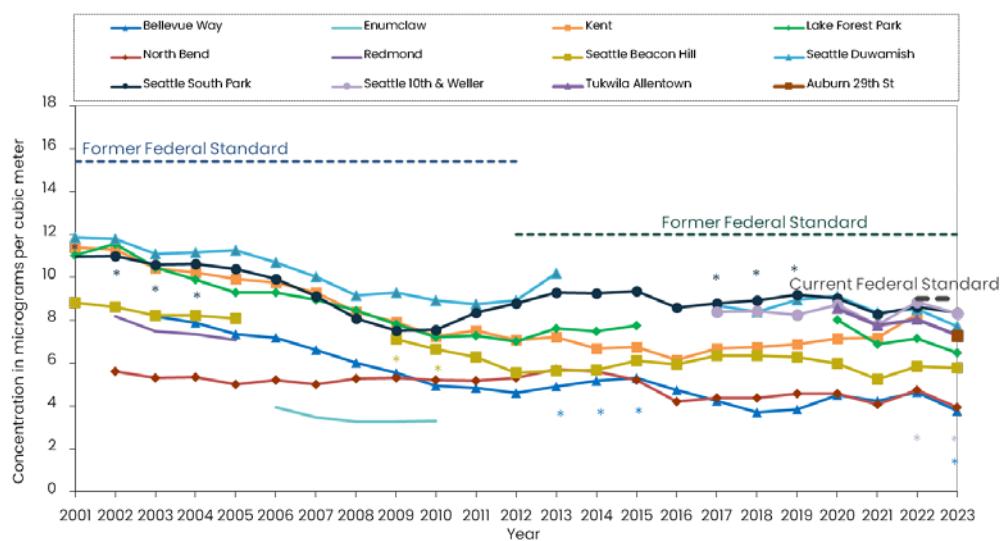

Figures 10 through 17 present 3-year average of annual concentrations at each monitoring station for King, Kitsap, Pierce, and Snohomish Counties. In February 2024, the EPA strengthened the annual standard from 12 $\mu\text{g}/\text{m}^3$ to 9 $\mu\text{g}/\text{m}^3$. All counties have levels below the 9 $\mu\text{g}/\text{m}^3$ annual standard. Since the standard was revised after 2023, we are continuing to display the older standard as “current standard”. Figures 12 and 13 do not show any 2012–2014 data for Kitsap County because the Bremerton monitoring site moved to a new location and design values could not be computed until three complete years of data were collected at the new site.

Figures 10 through 17 include data from the federal reference method (FRM) and continuous method monitors. The federal standard is based on a 3-year average, and each value on the graph is an average of the current year and the two prior years. For example, the value shown for 2023 is the average of the annual averages for 2021, 2022, and 2023. As with the daily standard, for each county we include two figures: the first shows the entire dataset, and the second shows levels with wildfire smoke-impacted days removed in 2017, 2018, 2020, 2021, 2022, and 2023.

PM_{2.5} Continuous Data and Seasonal Variability

Continuous monitoring data provide information on how PM_{2.5} levels vary throughout the year. For example, many sites have elevated PM_{2.5} levels during the winter when residential wood burning and air stagnations are at their peak but have low levels of PM_{2.5} during the summer. A summary of the continuous data for PM_{2.5}, black carbon, and ozone for the year 2023 is available at <https://pscleanair.gov/615/Data-Summary>. For more detailed information on continuous data, please see the Air Graphing tool at <https://secure.pscleanair.org/airgraphing> to plot the sites and timeframes of interest.

PM₁₀: Annual Standard and Modeled Concentrations

Our region was nonattainment for PM₁₀ in 1987 in the three industrial areas of Puget Sound: Seattle Duwamish Valley, Tacoma Tideflats, and Kent. The streets were paved, and the area saw significant reductions thereafter and levels were far below the standard since. Our region completed all its [limited maintenance plan](#) obligations in 2020, including monitoring for PM₁₀.

While the direct monitoring of PM₁₀ concentrations ended in 2007, we can still model recent concentration levels of PM₁₀ using the observed PM_{2.5} concentrations and two site-dependent linear relationships (one for summer (Apr-Sep) and one for winter (Oct-Mar)). These relationships were established for the 1999–2007 time-period when PM₁₀ & PM_{2.5} were both recorded at our sites. The main assumption with that method is that the linear relationships remained constant over time.⁴

In Table 3 and Table 4, we present the design values (DVs) that have been calculated using both a table-look-up method and a statistical-fit method, described in the EPA PM₁₀ State Implementation Plan (SIP) Development Guideline⁵. We did these calculations for the following sites: Kent (AQS Site ID: 53 033 2004), Seattle-Duwamish (53 033 0057), and Tacoma Tideflats (53 053 0031) PM₁₀ Maintenance Areas and for the last five years (2018–2023).

The DVs presented in Table 3 and Table 4 are calculated following two scenarios:

- **Scenario 1 (Table 3):** All daily modeled PM₁₀ concentrations are included in the DV calculation.
- **Scenario 2 (Table 4):** Daily modeled PM₁₀ concentrations are excluded from the DV calculation during 2017, 2018, 2020, 2021 & 2022 wildfire-smoke days (I-Flags^{6,7,8,9,10,11}).

Five-year DVs less than 98 µg/m³ were required to continue to qualify for the Limited Maintenance Plan (LMP)⁹. Over the last three years, scenario 1 (with wildfire smoke days included) would not have met this qualification. Scenario 2 would have met the qualification and is a more appropriate

⁴ The PM_{2.5} concentrations come from several instruments at each site. At all sites, we prioritize instruments measuring PM_{2.5} concentrations with missing values in the following way: FEM BAM > 1400ab/8500 FEM TEOM > 1405 FEM TEOM > nephelometer. While Kent and Seattle-Duwamish have most of their data coming from TEOM (2013–2018) and BAM (2018–2021), only a nephelometer has been in operation at Tacoma-Tideflats for 2013–2021. As of May 26, 2021, a BAM has been added a Tacoma-Tideflats and its data will be used next year once a full year of monitoring will be completed.

⁵ PM₁₀ SIP Development Guideline – United States Environmental Protection Agency. June 1987. EPA-450/2-86-001

⁶ The Tacoma Tideflats monitoring site experienced higher than typical firework activity in the late June – early July of 2021 leading to July 4th with elevated PM_{2.5} concentrations explaining the higher 2021 DV.

2023 Air Quality Data Summary

estimate for the Puget Sound region's three former Maintenance Areas, given the unprecedented wildfire smoke levels witnessed in summers of 2017, 2018, 2020, 2021, 2022 & 2023.

Table 3: Five-year DVs for PM₁₀ concentrations for 2017–2023 – scenario 1

Sites:	5-yr PM ₁₀ DVs – Scenario 1						
	2017	2018	2019	2020	2021	2022	2023
Kent*	89±25 (82)	115±35 (118)	115±37 (118)	226±98 (214)	226±98 (214)	225±104 (214)	
Seattle	72±11 (80)	119±45 (110)	117±46 (101)	216±104 (192)	216±103 (192)	217±102 (192)	210±122 (192)
Tacoma	93±39 (94)	163±69 (165)	163±70 (165)	234±92 (240)	232±90 (240)	229±96 (240)	214±114 (157)

Table 4: Five-year DVs for PM₁₀ concentrations for 2017–2023 – scenario 2

Sites:	5-yr PM ₁₀ DVs – Scenario 2						
	2017	2018	2019	2020	2021	2022	2023
Kent*	54±6 (53)	62±12 (65)	60±13 (64)	54±13 (44)	55±12 (56)	51±13 (43)	
Seattle	53±3 (56)	52±3 (53)	48±4 (48)	46±3 (46)	46±3 (48)	42±4 (43)	41±3 (41)
Tacoma	60±16 (55)	60±12 (58)	59±13 (58)	59±14 (57)	73±25 ⁶ (67)	73±26 ⁶ (67)	82±43 ⁶ (67)

Values appear as DV ± an uncertainty interval from a lognormal fit to the data and its 95% prediction interval. Parenthetical values are the DVs obtained using the table-look-up method.⁵

* Kent site monitoring stopped on 6/19/2023 as site had to be shutdown until a new location is found.

Particulate Matter – PM_{2.5} Speciation and Aethalometers

Although there are no regulatory requirements to go beyond measuring the total mass of fine particulate matter, it is beneficial to know its chemical makeup in addition to its mass. Knowledge about the composition of fine particulate can help guide emissions reduction strategies, such as the Agency's commitment to reducing wood smoke and diesel particulate emissions,^{8,9,10} and is useful to scientific and health researchers investigating questions about the effects of fine particulate matter on human health and the environment.

Aethalometer Data

Aethalometers provide information about the carbon fraction of fine particulate matter. Aethalometers continuously measure light absorption at seven different optical wavelengths to estimate carbon concentrations. Two of these wavelengths are important in our evaluation: black carbon (BC) and ultraviolet (UV). Measurements from the black carbon channel correlate well with elemental carbon (EC) concentrations derived from speciation data. Measurements from the UV channel help produce a qualitative estimate of organic carbon (OC), which is correlated with the difference between the UV and BC channel measurements (UV-BC). Elemental and organic carbon are related to diesel particulate, wood smoke particulate, and particulate from other combustion sources.¹¹ Unfortunately, neither is uniquely attributed to a particular combustion type, so the information gained from aethalometer data is qualitative.

The Agency maintains aethalometers at monitoring sites with high particulate matter concentrations, as well as sites with speciation data, so that data from the different methods to measure carbon may be compared. Figure 18 shows annual average trending of black carbon concentrations. Since 2003, the general trend shows reducing BC levels. A statistical summary of aethalometer black carbon data is presented on page A-14 of the Appendix.

Ozone

Ozone is a summertime air pollution problem in our region and is not directly emitted by pollutant sources. Ozone forms when photochemical pollutants react with sunlight. These pollutants are called ozone precursors and include volatile organic compounds (VOC) and nitrogen oxides (NO_x), with some influence by carbon monoxide (CO). These precursors come from human activities such as transportation and solvent use, as well as natural sources. Ozone levels are usually highest in the afternoon because of the intense sunlight and the time required for ozone to form in the atmosphere. The Washington State Department of Ecology conducts ozone monitoring in our four counties.

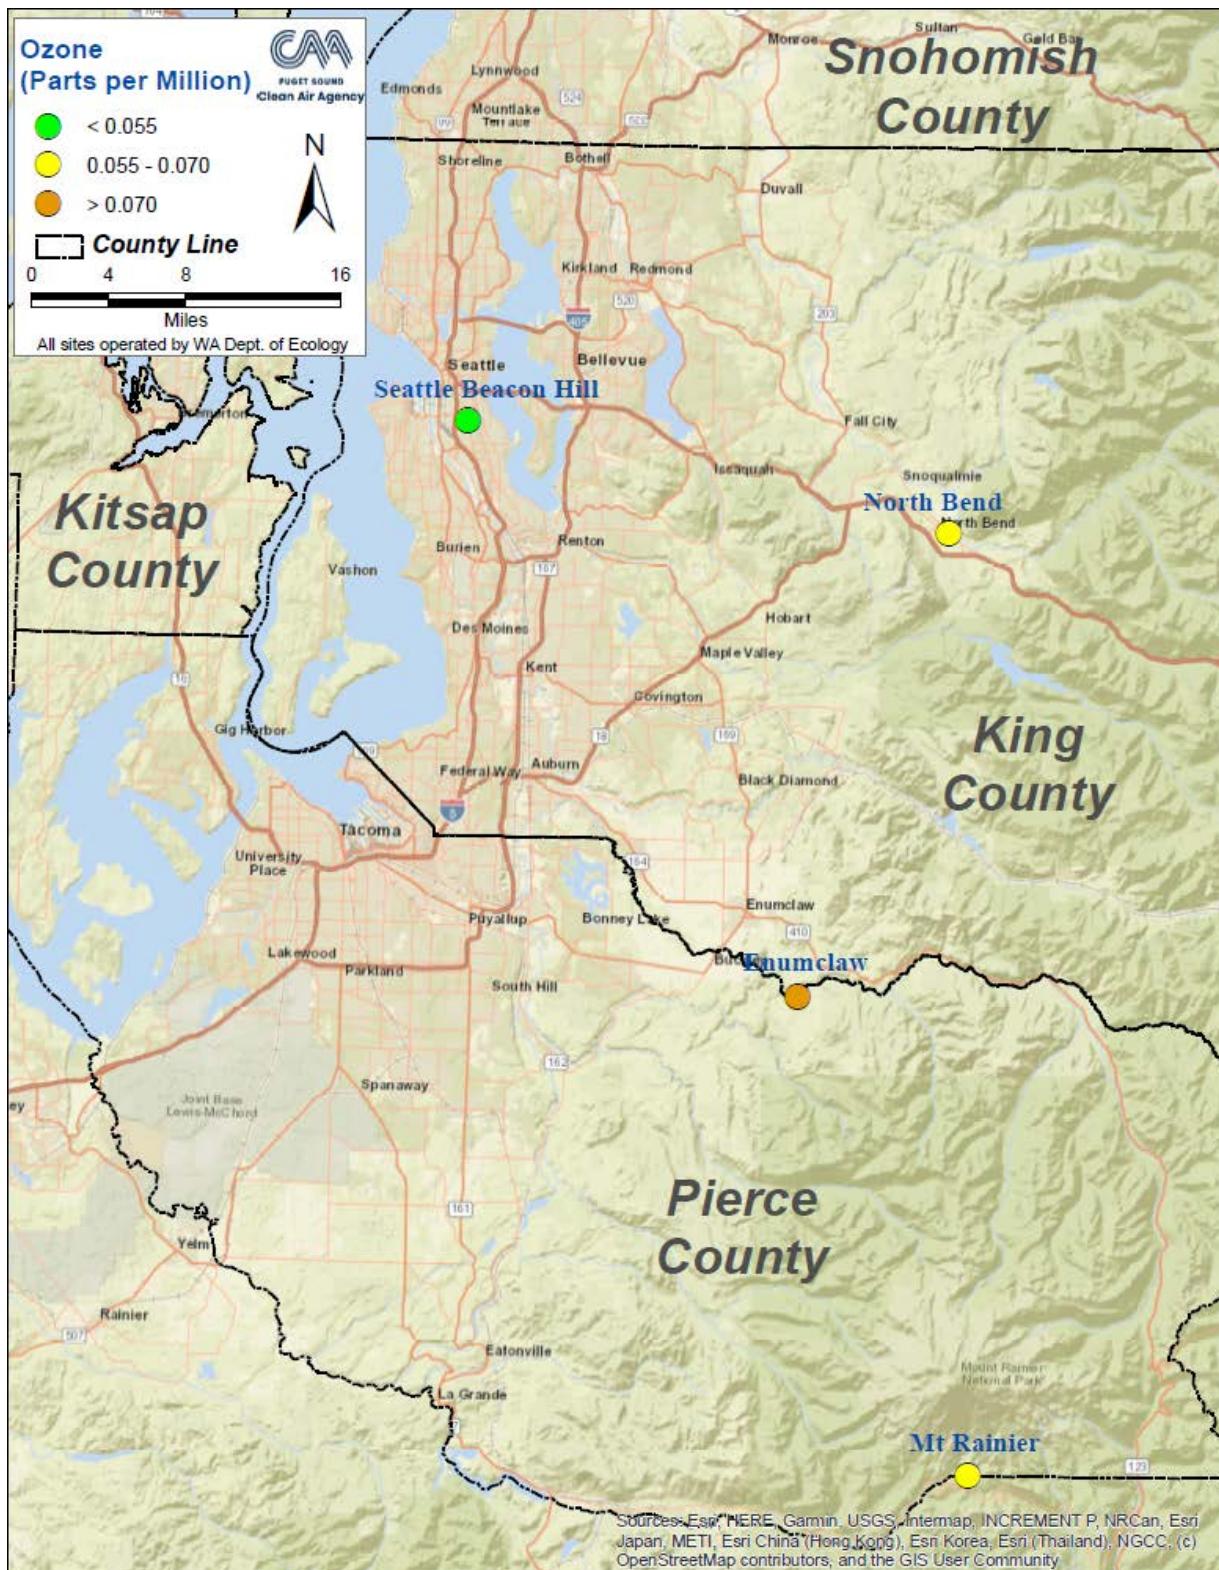

People sometimes confuse upper atmosphere ozone with ground-level ozone. Upper atmosphere, or stratospheric ozone, helps to protect the earth from the sun's harmful ultraviolet rays. In contrast, ozone formed at ground level is unhealthy. Elevated concentrations of ground-level ozone can cause reduced lung function and respiratory irritation and can aggravate asthma.¹² Ozone has also been linked to immune system impairment. People with respiratory conditions should limit outdoor exertion if ozone levels are elevated. Even healthy individuals may experience respiratory symptoms on a high-ozone day. Ground-level ozone can also damage forests and agricultural crops, interfering with their ability to grow and produce food.¹³

Most ozone monitoring stations are located in rural areas of the Puget Sound region in the western foothills of the Cascade Mountains, while the precursor chemicals that react with sunlight to produce ozone are generated primarily in large metropolitan areas (mostly by cars and trucks). The photochemical formation of ozone takes several hours, and the highest concentrations of ozone are measured in the communities downwind of these large urban areas. In the Puget Sound region, the hot sunny days favorable for ozone formation also tend to have light north-to-northwest winds. Map 3 shows the ozone monitoring network and the design values (three-year average of the 4th highest concentrations) measured in 2021-2023.

Map 3: Ozone 3-year Average of 4th Highest 8-hr Value for 2023

2023 Air Quality Data Summary

Figures 19 and 20 present data for each monitoring station and the 8-hour federal standard. Figure 19 shows levels with the entire dataset, and Figure 20 shows ozone levels with wildfire smoke impacted days removed in 2017, 2018, 2020, 2021, 2022, and 2023. The federal standard is based on the 3-year average of the annual 4th highest 8-hour concentration, called the “design value”. The year on the x-axis represents the last year averaged. For example, concentrations shown for 2023 are an average of 2021, 2022, and 2023 4th highest concentrations.

The EPA’s 2015 8-hour standard is 0.070 ppm. The highest 2023 site design value (for the entire dataset, including wildfire smoke impacted days) is 0.073 ppm at the Enumclaw site. This site would not be considered nonattainment at this time due to the wildfire smoke influence that could be excluded. The 2023 design value for the Enumclaw site when wildfire smoke impacted days are excluded is 0.067 ppm. All other monitoring sites are below the standard value of 0.070 ppm.

Statistical summaries for 8-hour average ozone data are provided on page A-15 of the Appendix.

For additional information on ozone, visit <https://www.epa.gov/ozone-pollution>.

Figure 19: Ozone for Puget Sound Region

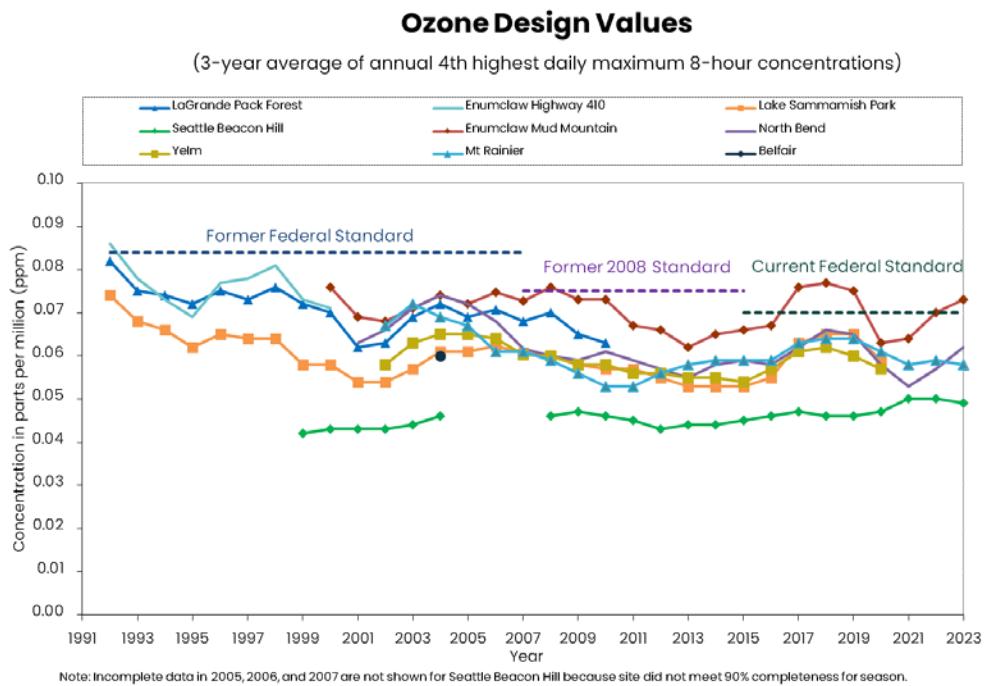

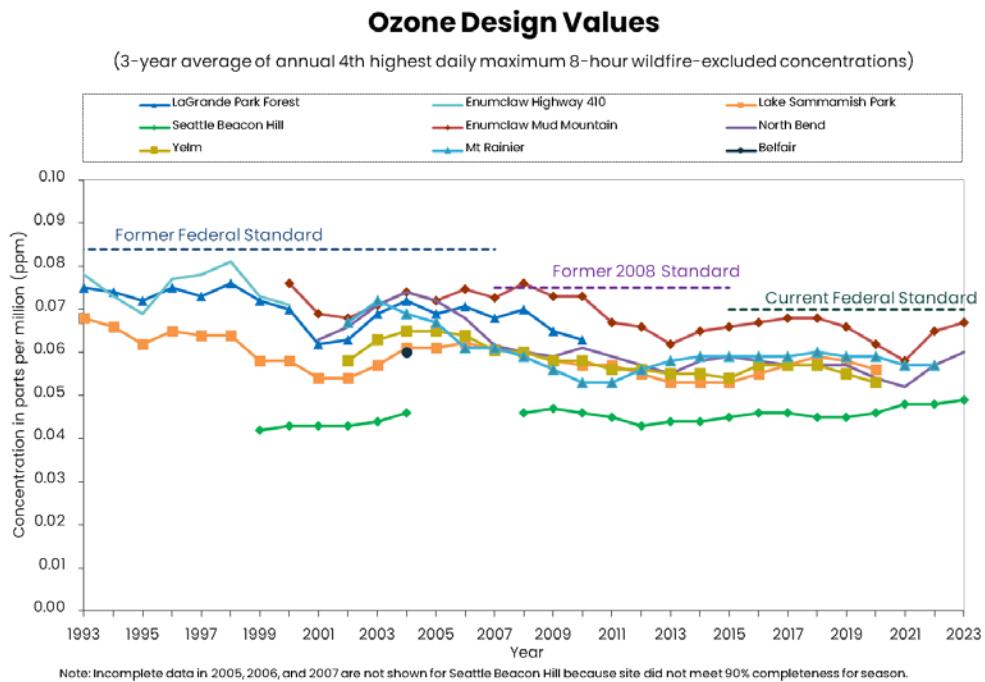

Figure 20: Ozone for Puget Sound Region with wildfire impacted days removed

Nitrogen Dioxide

Nitrogen dioxide (NO_2) is a reddish brown, highly reactive gas that forms from the reaction of nitrogen oxide (NO) and hydroperoxy (HO_2) and alkylperoxy (RO_2) free radicals in the atmosphere. NO_2 can cause coughing, wheezing and shortness of breath in people with respiratory diseases such as asthma.¹⁴ Long-term exposure can lead to respiratory infections.

The term NO_x is defined as $\text{NO} + \text{NO}_2$. NO_x participates in a complex chemical cycle with volatile organic compounds (VOCs) which can result in the production of ozone. NO_x can also be oxidized to form nitrates, which are an important component of fine particulate matter. On-road vehicles such as trucks and automobiles and off-road vehicles such as construction equipment, marine vessels and port cargo-handling equipment are the major sources of NO_x in our region. Industrial boilers and processes, home heaters, and gas stoves also produce NO_x .

Motor vehicle and non-road engine manufacturers have been required by EPA to reduce NO_x emissions from cars, trucks, and non-road equipment. As a result, emissions have declined dramatically since the 1970s.

EPA promulgated a 1-hour national ambient air quality standard for nitrogen dioxide on January 22, 2010.¹⁵ Since then, Department of Ecology added two “near-road” monitoring sites very close to Interstate 5: one in Seattle (10th & Weller), and one in Tacoma (South 36th St.). To learn more about the monitoring method visit <https://www.epa.gov/amtic/near-road-monitoring>

In addition to the near-road sites, the Department Ecology measures nitrogen dioxide at the Seattle Beacon Hill site. The monitoring method now records NO_y instead of NO_x , in order to observe all reactive nitrogen compounds. NO_y is NO_x plus all other reactive nitrogen oxides present in the atmosphere. NO_y components such as nitric acid (HNO_3) and peroxyacetyl nitrate (PAN) can be important contributors to the formation of ozone and fine particulate matter. Direct NO_2 measurements at Beacon Hill using Cavity Attenuated Phase Shift (CAPS) spectroscopy technique started in 2020.

Figure 21 shows NO_2 concentrations for Beacon Hill through 2005. In 2006, no data were recorded due to the relocation of the Beacon Hill monitor to a different location on the same property. From 2007 until 2020 at Beacon Hill, the concentration of NO_2 is represented as $\text{NO}_y - \text{NO}$, since NO_2 was no longer directly recorded, and $\text{NO}_y = \text{NO} + \text{NO}_2 + \text{other nitroxyl compounds}$.

The 2010 1-hour standard is 100 ppb and is based on the 98th percentile of 1-hour daily maximum concentrations, averaged over three years. Nitrogen dioxide levels in the Puget Sound region, as currently monitored by Ecology, are typically below (cleaner than) the 1-hour standard. The 1-hour

standard is depicted in Figure 21 with historical data since 1998. The years prior to 2010 have been included on the graphs for historical comparison.

Visit epa.gov/airquality/nitrogenoxides/ for additional information on NO₂.

Figure 21: Nitrogen Dioxide (NO₂) (1998-2005; 2017-2023) and Reactive Nitrogen (NO_y - NO) (2007-2023) for the Puget Sound Region

Carbon Monoxide

Carbon monoxide (CO) is an odorless, colorless gas that can enter the bloodstream through the lungs and reduce the amount of oxygen that reaches organs and tissues. Carbon monoxide forms when the carbon in fuels does not burn completely. Most of the CO emissions come from motor vehicles.

Elevated levels of CO in ambient air occur more frequently in areas with heavy traffic and during the colder months of the year when temperature inversions are more common. People with cardiovascular disease or respiratory problems may experience chest pain and increased cardiovascular symptoms, particularly while exercising, if CO levels are high. High levels of CO can affect alertness and vision even in healthy individuals.

Although urban portions of the Puget Sound region have historically violated the CO standard, CO levels have decreased significantly primarily due to emissions controls on car engines. EPA designated the Puget Sound region as a CO attainment area in 1996. Ecology has substantially reduced its CO monitoring network, and only the Beacon Hill site remains from the historical network. The near-road site at 10th & Weller began operation in June 2014. There currently are no CO monitoring stations in Kitsap, Pierce, or Snohomish Counties.

The CO national ambient air quality standard is based on the 2nd highest 8-hour average using the procedures published in the federal register. The EPA also has a 1-hour standard for CO of 35 ppm, not to be exceeded more than once a year. Measured 1-hour concentrations in the Puget Sound area are typically much lower than the 35 ppm standard.

For a historic look at the Puget Sound region's carbon monoxide levels, please see the 2015 Air Quality Data Summary which is available on our website at www.pscleanair.gov/DocumentCenter/View/2294/Air-Quality-Data-Summary-2015PDF.

For additional information on CO, visit epa.gov/airquality/carbonmonoxide.

Sulfur Dioxide

Sulfur dioxide (SO_2) is a colorless, reactive gas produced by burning fuels containing sulfur, such as coal and oil, and by industrial processes. Historically, the greatest sources of SO_2 were industrial facilities that derived their products from raw materials such as metallic ore, coal, and crude oil, or that burned coal or oil to produce process heat (petroleum refineries, cement manufacturing and metal processing facilities). Marine vessels, on-road vehicles, and diesel construction equipment are the main contributors to SO_2 emissions today.

SO_2 may cause people with asthma who are active outdoors to experience bronchial constriction, the symptoms of which include wheezing, shortness of breath and tightening of the chest. People should limit outdoor exertion if SO_2 levels are high. SO_2 can also form sulfates in the atmosphere, a component of fine particulate matter.

The Puget Sound area has experienced a significant decrease in SO_2 from sources such as pulp mills, cement plants and smelters in the last two decades.

In 1971, the EPA set an annual SO_2 standard of 0.03 ppm and a 24-hour standard of 0.14 ppm that could not be exceeded more than once a year. EPA changed the SO_2 standard in June of 2010 to a shorter-term (1-hour) standard of 0.075 ppm (75 ppb) and revoked the former annual and daily average standards. Historic comparisons to federal and Washington State standards can be seen in our 2009 data summary which is available upon request.

The 2010 standard is a 3-year average of the 99th percentile of the daily 1-hour maximum concentrations. Levels must be below 75 ppb. Sulfur dioxide levels at the Seattle Beacon Hill site have been below the 2010 standard from 2011–2023.

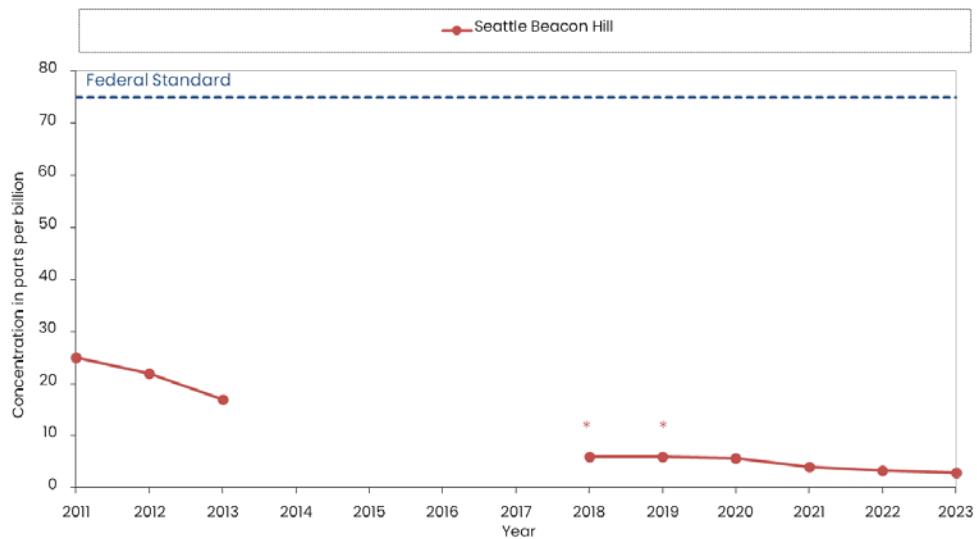

Figure 22 shows the maximum 3-year average of the 99th percentile of 1-hour maximum concentrations at Beacon Hill which have stayed within the standard.

Additional information on SO_2 is available at <https://www.epa.gov/so2-pollution>.

Figure 22: Sulfur Dioxide (SO₂) 1-Hour Maximum Concentrations (3-Year Average of the 99th Percentile) for the Puget Sound Region

Sulfur Dioxide Estimated Design Values

(3-year average of 99th percentile of 1-Hour average daily maximum concentrations)

Note: 2011 was the first year that the Design Value has been calculated and compared to the revised primary SO2 standard.

* Indicates an estimate based on incomplete data. Data less than 75% for a quarter at Beacon Hill in 2016 & 2017.

Lead

Lead is a highly toxic metal that was used for many years in household products such as paints, transportation fuel, and industrial chemicals. Now that lead has been banned from paint and most fuels, the greatest sources of lead emissions, nationally, are industrial processes (particularly primary and secondary lead smelters) and battery manufacturers. And while lead has been removed from fuel for large aircraft, lead found in aviation gasoline (avgas), used by small aircraft, remains a concern nationally. For additional information on lead, visit <https://www.epa.gov/lead-air-pollution>.

People and animals are mainly exposed to lead by breathing it in and ingesting it in food, water, soil, or dust. Lead accumulates in the blood, bones, muscles, and fat. Infants and young children are especially sensitive to even low levels of lead. Lead can have health effects ranging from behavioral problems and learning disabilities to seizures and death.

Since the phase-out of lead in most fuels and the closure of the Harbor Island secondary lead smelter in Seattle in 1984, levels of lead in ambient air have decreased substantially. For a historic look at the Puget Sound region's lead levels, please see page 87 of the 2007 Air Quality Data Summary which is available [here](#).

In October 2008, EPA strengthened the lead standard from $1.5 \mu\text{g}/\text{m}^3$ to $0.15 \mu\text{g}/\text{m}^3$ (rolling three-month average).¹⁶ As part of this rulemaking, EPA initiated a pilot lead monitoring program that focuses on lead from aviation gasoline at small airports, including two in our region. Results are available here: <https://fortress.wa.gov/ecy/publications/SummaryPages/1302040.html>. EPA maintained this level in its 2016 review of the lead standard.

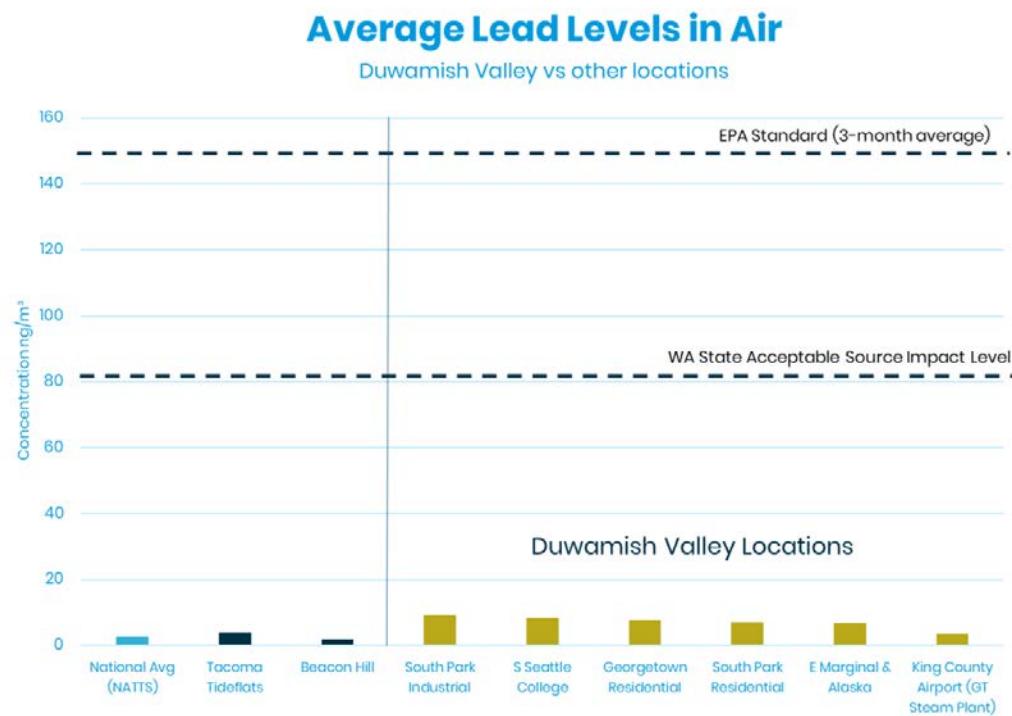

In 2022 we conducted an air toxics study where we measured air toxics at multiple sites in the Duwamish Valley in Seattle as well as Tacoma Tideflats and Seattle-Beacon Hill. Figure 23 shows the average lead levels sampled during the Air Toxics study. The dashed bars represent the EPA National Air Quality Standard for lead and the Washington State Acceptable Source Impact Level for permit screening as established by the Washington State Clean Air Act. The report for the Air Toxics Study is available here:

<https://pscleanair.gov/DocumentCenter/View/5369/2023TacomaSeattleAirToxicsReport>

¹⁶US EPA, National Ambient Air Quality Standard for Lead, Final Rule. Federal Register, November 12, 2008; <http://www.gpo.gov/fdsys/pkg/FR-2008-11-12/pdf/E8-25654.pdf>

2023 Air Quality Data Summary

Figure 23. Average lead levels sampled at temporary Duwamish Valley locations during the 2022 air toxics study.

Visibility

Visibility data is presented as an indicator of air quality. Visibility is explained in terms of visual range and light extinction. *Visual range* is the maximum distance, usually in miles or kilometers, at which a black object is visible against the horizon. *Light extinction* is the sum of light scattering and light absorption by fine particles and gases in the atmosphere. The more light extinction, the shorter the visual range.

Reduced visibility is caused by weather such as clouds, fog, rain, and air pollution, including fine particles and gases. The major contributor to reduced visual range is fine particulate matter ($PM_{2.5}$), which is present near the ground and can be transported aloft and may remain suspended for a week or longer. Figures 24 and 25 show visibility for the overall Puget Sound area, as well as 12-month moving average for King, Kitsap, Pierce and Snohomish Counties. Visibility on these graphs, in units of miles, is determined by continuous nephelometer monitoring. The nephelometer measures light scattering due to particulate matter (b_{sp}), and this value is converted into estimates of visibility in miles. Nephelometer data are shown on page A-13 of the Appendix.

The red line represents the monthly average visibility. The large fluctuations are due to seasonal variability. The blue line shows the average of the previous 12-months. This moving average reduces seasonal variation and allows longer-term trends to be observed. The moving average shows that the visibility for the Puget Sound area has steadily increased (improved) over the last decade with some year-to-year variability. For the 24-year period from December 1990 through December 2023, the 12-month moving average increased from 48 miles to 87 miles.

For additional information on visibility, visit <https://www.epa.gov/visibility>.

Figure 24: Puget Sound Visibility

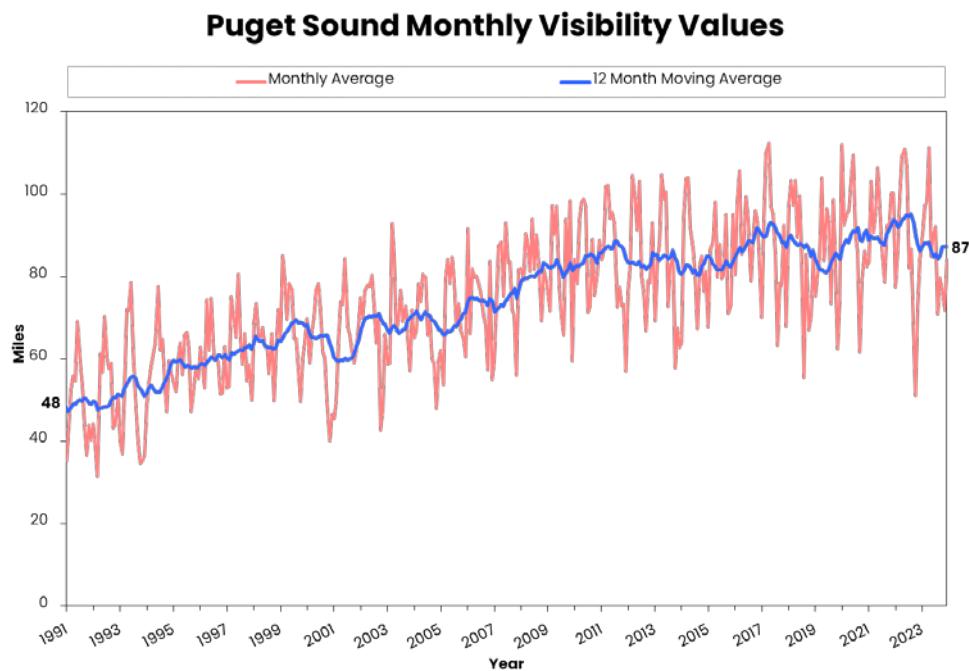

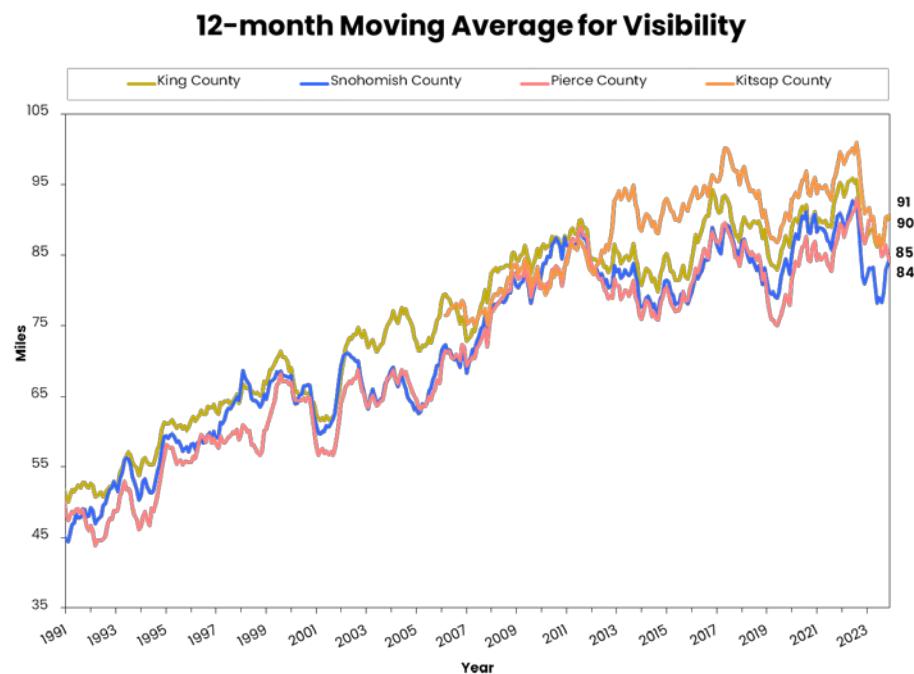

Figure 25: County-wide Visibility

Air Toxics

“Air toxics” are air pollutants known or suspected to cause health problems. Potential health effects include cancer, birth defects, lung damage, immune system damage, and nerve damage.^{17,18} The Agency considers over 400 different air pollutants air toxics.

This section presents a relative ranking of these toxics based on potential cancer risks, as well as trends over time. We provide a short description of each air toxic of concern, including their health effects and sources.

In 2021-2022, we completed an in-depth study of six locations in Tacoma and Seattle and finished a report in December 2023. The short summary report for the Air Toxics Study is available here:

<https://pscleanair.gov/DocumentCenter/View/5442/2023-Air-Toxics-Community-Report>

The full report for the Air Toxics Study is available here:

<https://pscleanair.gov/DocumentCenter/View/5369/2023TacomaSeattleAirToxicsReport>

Ecology monitors for air toxics at the Seattle Beacon Hill site. The Beacon Hill site is one of 27 EPA-sponsored National Air Toxic Trends Sites across the country.¹⁹ As in previous years, Ecology monitored toxics every six days. The 2006 dataset is incomplete due to relocation of the Beacon Hill site that year; and the 2020 dataset is the average of only seven months and does not include some summer samples as the air toxics sampling could not be conducted from mid-March to July due to COVID-19. The 2023 carbonyl and VOC datasets are an average of six months. The samplers from late June through the end of the year were sampling room air instead of ambient air so were invalidated. The 2023 PAH and PM₁₀ metals were not affected. For general information on air toxics, see www.pscleanair.gov/162/Air-Toxics. Air toxics statistical summaries are provided starting on page A-16 of the Appendix.

Relative ranking based on cancer risk & unit risk factors

Table 5 below ranks 2023 air toxics from the Seattle Beacon Hill monitoring site according to mean potential cancer risk per million people. It shows monitored pollutants ranked from highest concern (#1) to lowest, based on ambient concentrations multiplied by unit risk factors. A unit risk factor takes into account how toxic or carcinogenic a pollutant is. Cancer risk estimates are shown here to provide a meaningful basis of comparison between pollutants and are not intended to represent any one community's or individual's exposure.

PUGET SOUND

Clean Air Agency

2023 Air Quality Data Summary

Since the release of the 2018 Air Quality Data Summary, Ecology released an updated list of cancer risk factors, known as the Ambient Source Impact Level (ASIL) table.²⁰ The main reason for this update was to align the ASIL table with the latest scientific data. Ecology does not determine the unit risk factors that are the basis of the table, but rather uses values from three authoritative sources: the EPA's Integrated Risk Information System (IRIS); the California Office of Environmental Health Hazard Assessment (OEHHA), and the U.S. Agency for Toxic Substances and Disease Registry (ATSDR). Many unit risk factors were updated by these agencies between the last ASIL update, in 2009, and 2019, leading to sometimes significant changes in the predicted risk. In some cases, the predicted risks have increased, such as with ethylene oxide, while in others, they have decreased, such as with carbon tetrachloride. These changes do not mean that the inherent risk of these pollutants has changed, but rather that our scientific understanding of the risk has improved, and we now have better estimates of their carcinogenicity.

Potential cancer risk is an estimate of the number of potential additional cancers (out of a population of one million) that may develop from exposure to air toxics over a lifetime (set at 70 years). A risk threshold of one in one million is commonly used as a screening value and is used here.²¹ For details on how air toxics were ranked, please see page A-17 in the Appendix.

Risks presented in this table are based on annual average ambient (outside) concentrations. Risks based on 95th percentile concentrations (a more conservative statistic than presented in Table 5) are presented on page A-18 of the Appendix. Page A-18 also lists the frequency (percentage) of samples that were over the cancer screening level of one in a million risk.

Two of the air toxics that present the greatest potential health risk in the Puget Sound area, diesel particulate matter and wood smoke particulate, are not included in the table. No direct monitoring method currently exists for these toxics. Modeling for these air toxics was not conducted for this report, however, the Agency has estimated the cancer risk for these parameters in recent studies.^{22,23} Diesel Exhaust risk estimates can range from 400–600 per million in near-road and industrial areas; whereas the cancer risk from wood smoke can range from 20–30 per million in wood smoke impacted areas.

Table 5: 2023 Beacon Hill Air Toxics Ranking

(Average Potential Cancer Risk Estimate per 1,000,000)

Air Toxic	Rank	Average Potential Cancer Risk ^a
Ethylene oxide	1	1695 ^b
Formaldehyde	2	9
Hexavalent Chromium	3	5 ^c
Carbon tetrachloride	4	3
Benzene	5	3
Acetaldehyde	6	2
Chloroform	7	2
Acrolein - Verified	8	2
Arsenic (PM10)	9	2 ^d
Naphthalene (TSP) STP	10	1
1,3-Butadiene	11	<1
Acrylonitrile	12	<1

^a Risk based on unit risk factors as adopted in Washington State Acceptable Source Impact Level Table, 2019 update (WAC 173-460-150)²⁴

^b Ethylene oxide levels are very near detection limits. These values may not represent the risk accurately and may be subject to method bias.

^c Sampling for hexavalent chromium was discontinued in 2013 and the included estimate is based on 2013 data using 2019 ASILs.

^d PM₁₀ metals data for 2023 not available at the time of this Report. This value is from 2022.

Health effects other than cancer

Air toxics can also have chronic non-cancer health effects. These include respiratory, cardiac, immunological, nervous system, and reproductive system effects.

To determine non-cancer health risks, we compared each air toxic to its chronic reference exposure level, as established by California EPA (the most comprehensive dataset available)²⁵. A chronic reference exposure level (chREL) is considered a safe level of continuous exposure to an individual air toxic for non-cancer health effects.

Only one air toxic, acrolein, failed the screen for non-cancer chronic health effects, with measured concentrations consistently exceeding the chREL. Acrolein irritates the lungs, eyes, and nose, and is a

²⁴Washington State Administrative Code WAC 173-460-150, apps.leg.wa.gov/WAC/default.aspx?cite=173-460-150

²⁵ <https://oehha.ca.gov/air/general-info/oehha-acute-8-hour-and-chronic-reference-exposure-level-rel-summary>

combustion by-product.²⁶ A table of reference concentrations and hazard indices for each air toxic measured in the last year with a hazard index greater than zero is on page A-19 of the Appendix. A hazard index is the concentration of a pollutant (either mean or other statistic) divided by the reference concentration. Typically, no adverse non-cancer health effects for that pollutant are associated with a hazard index less than 1, although it is important to consider that people are exposed to many pollutants at the same time. We did not explore acute non-cancer health effects, which are based on 1-hour measurements, because the Beacon Hill air toxics measurements are made on 24-hour samples.

PM₁₀ Metals

PM₁₀ metals data for 2023 were not available at the time of this Report. We will be. In this Report all PM₁₀ metals values will be from 2022. The 2023 values will be presented in the 2024 Data Summary.

Air toxics trends

Trends in annual average cancer risks are shown on the following pages for the highest-ranked air toxics measured at Seattle Beacon Hill from 2000 to 2023. For many air toxics, our analysis of the trends shows a statistically significant decrease in annual average concentrations. EPA has not set ambient air standards for air toxics, so graphs do not include reference lines for federal standards. A statistical summary of the trends shown on the following pages can be found on page A-20 of the Appendix.

²⁶EPA, Acrolein Hazard Summary; <https://www.epa.gov/sites/production/files/2016-08/documents/acrolein.pdf>.

Ethylene Oxide

The EPA lists ethylene oxide as a known human carcinogen. Ethylene oxide inhalation is associated with increased risk of blood cancers and of breast cancer in women.²⁷ Its main use is as a chemical intermediate in the production of ethylene glycol (antifreeze), but it is also used as a fumigating agent for spices and cosmetics, and a sterilizing agent for medical supplies. Ethylene oxide's 2023 average potential cancer risk estimate at Seattle Beacon Hill was 1695 in one million. The 2023 average is only from samples from 1/1/2023 - 6/23/2023 due to all samples after 6/23/2023 being invalidated.

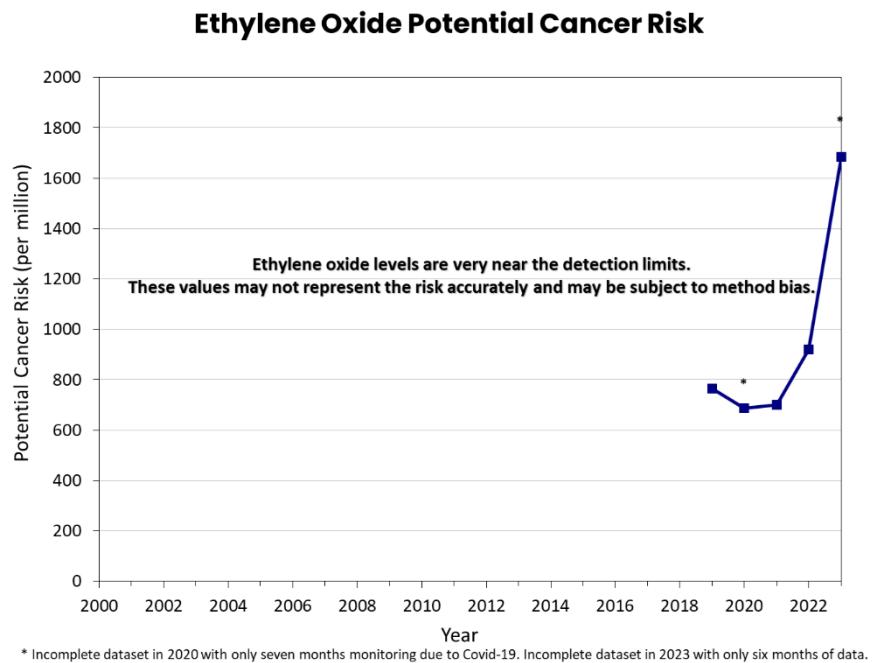

It was added to the suite of air toxics measured at Beacon Hill mid-year in 2018. In the 2018 ASIL update, ethylene oxide's unit risk factor was made more stringent by a factor of 57 (from 0.0114 to 0.0002). In 2019, ethylene oxide sampling across the country showed that the Seattle Beacon Hill monitor was one of the lowest across the country.²⁸ A significant increase was observed in 2023. This increase was mostly driven by four anomalous sampling days. Without the three anomalous sampling days the Potential Cancer Risk is 1139 per million, which is slightly higher than previous years. The 2023 average is only from samples from 1/1/23 - 6/23/2023. All samples after 6/23/2023 were invalidated so this average is not representative of the entire year. As the ASIL is well below the detection limit, the annual average value has a significant degree of uncertainty (well over 100 per million potential cancer risk). The Agency is working alongside the EPA to determine key sources of ethylene oxide and reduction strategies.²⁹

Figure 26: Ethylene Oxide Annual Average Potential Cancer Risk at Beacon Hill, 2019–2023

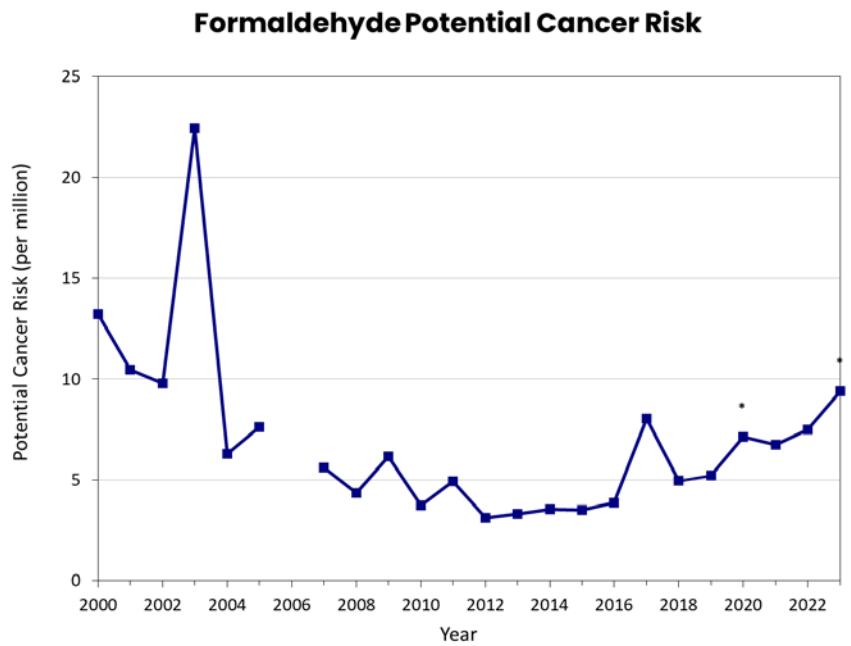

Formaldehyde

The EPA lists formaldehyde as a probable human carcinogen. Formaldehyde inhalation is also associated with eye, nose, throat, and lung irritation.³⁰ Sources of ambient formaldehyde include automobiles, trucks, wood burning and other combustion. Formaldehyde's 2023 average potential cancer risk estimate at Beacon Hill was 9.4 in one million. The 2023 average is only from samples from 1/1/2023 - 6/23/2023 due to all samples after 6/23/2023 being invalidated.

The sharp increase in average formaldehyde concentration in 2003 was due to nine anomalous sampling days in July 2003 when levels were roughly ten times the normal levels. It is possible that a local formaldehyde source was present at the Beacon Hill reservoir during this month and inadvertently affected the monitors.

Agency efforts that target vehicle exhaust and wood stove emission reductions also reduce formaldehyde emissions. We did not find a statistically significant trend in formaldehyde over time.

Figure 27: Formaldehyde Annual Average Potential Cancer Risk at Beacon Hill, 2000–2023

³⁰EPA Hazard Summary; <https://www.epa.gov/sites/production/files/2016-09/documents/formaldehyde.pdf>.

Hexavalent Chromium

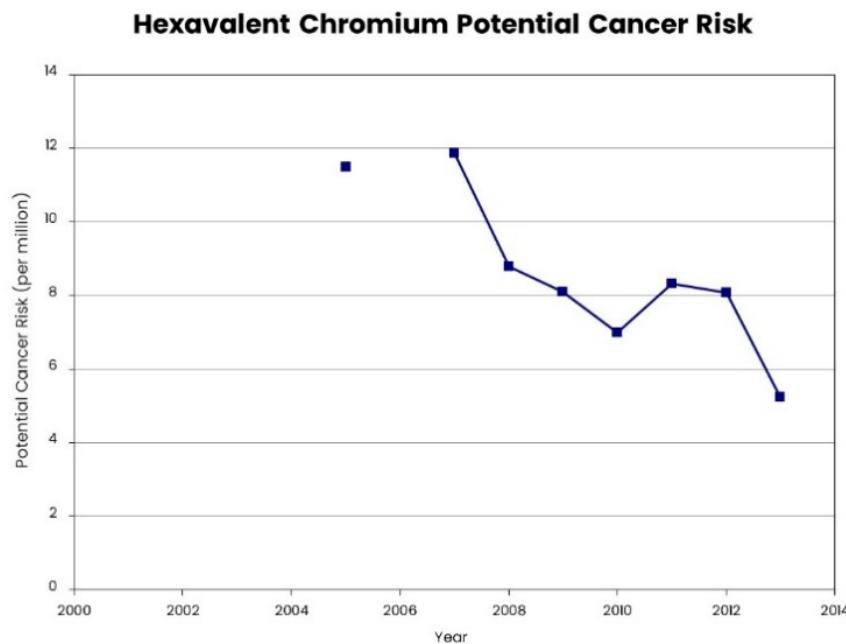

Chromium is present in two chemical states (trivalent and hexavalent) in our air. Trivalent chromium occurs naturally, while hexavalent comes from human activities and is much more toxic. EPA lists hexavalent chromium as a known carcinogen, associated primarily with lung cancer. Hexavalent chromium is often abbreviated as chromium +6 or chromium (VI).

Exposure to hexavalent chromium is also associated with adverse respiratory, liver, and kidney effects.³¹ Sources of hexavalent chromium include industrial processes such as chrome electroplating, as well as combustion of distillate oil, green glass production, and combustion of gasoline and diesel fuels (car, truck, and bus exhaust).

Due to the significant cost of monitoring for this pollutant, monitoring for total suspended particulate (TSP) hexavalent chromium was stopped in June 2013. The 2013 estimated average potential cancer risk for hexavalent chromium at Beacon Hill was 3 in one million based on the first half of the year.

In some years, up to 20% of the samples were below method detection limits. For the trend below, we used Kaplan-Meier analysis to estimate the annual means, as this method is designed to overcome bias from samples below the detection limit and other forms of censored data. Since 2000, we found a statistically significant drop in risk from hexavalent chromium at an average rate of about 0.7 per million per year. The Agency's permitting program works with and regulates industrial chromium plating operations to reduce hexavalent chromium emissions.

Figure 28: Hexavalent Chromium Annual Average Potential Cancer Risk at Beacon Hill, 2005–2013

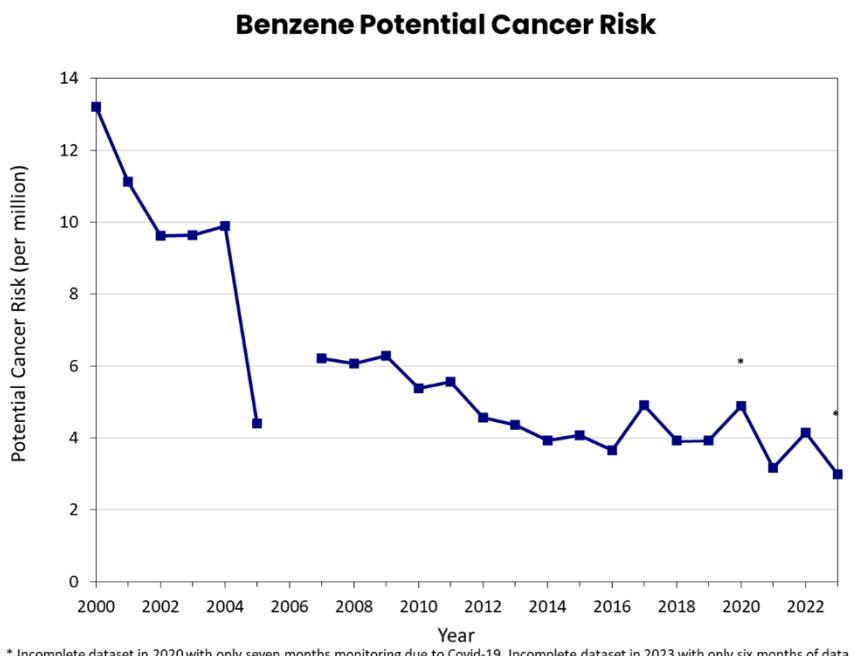

³¹EPA Hazard Summary: <https://www.epa.gov/sites/production/files/2016-09/documents/chromium-compounds.pdf>.

Benzene

The EPA lists benzene as a known human carcinogen. Benzene inhalation is also linked with blood, immune and nervous system disorders.³² This air toxic comes from a variety of sources, including car/truck exhaust, wood burning, evaporation of industrial solvent and other combustion. Benzene's 2023 average potential cancer risk estimate at Beacon Hill was 3 in one million. The 2023 average is only from samples from 1/1/2023 - 6/23/2023 due to all samples after 6/23/2023 being invalidated.

Benzene levels are likely decreasing in our area due to factors including less automobile pollution with cleaner vehicles coming into the fleet, better fuels, and fewer gas station emissions due to better compliance (vapor recovery at the pump and during filling of gas station tanks). We have found a statistically significant drop in risk from benzene at an average rate of about 0.33 per million per year since 2000.

Figure 29: Benzene Annual Average Potential Cancer Risk at Beacon Hill, 2000–2023

³²EPA Hazard Summary; <https://www.epa.gov/sites/production/files/2016-09/documents/benzene.pdf>.

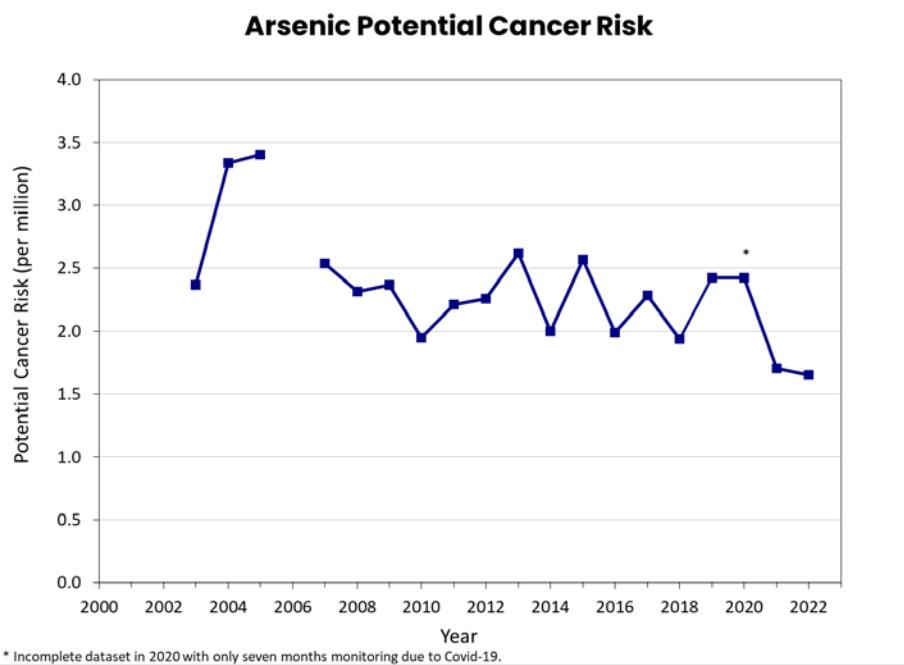

Arsenic (2022)

PM10 metals data for 2023 was not available at the time of this Report. This value is from 2022.

EPA lists arsenic as a known carcinogen. Exposure to arsenic is also associated with skin irritation and liver and kidney damage.³³ Arsenic is used to treat wood and in colored glass. Combustion of distillate oil is also a source of arsenic in the Puget Sound area. Arsenic's 2022 average potential cancer risk estimate at Beacon Hill was 2 in one million. Since 2000, we found a statistically significant drop in risk from arsenic at an average rate of about 0.05 per million per year.

The Agency's permitting program works with and regulates industrial users of arsenic to reduce emissions. Illegal burning, especially of treated wood, can also contribute to arsenic emissions in our area.

Figure 30: Arsenic Annual Average Potential Cancer Risk at Beacon Hill, 2003–2022

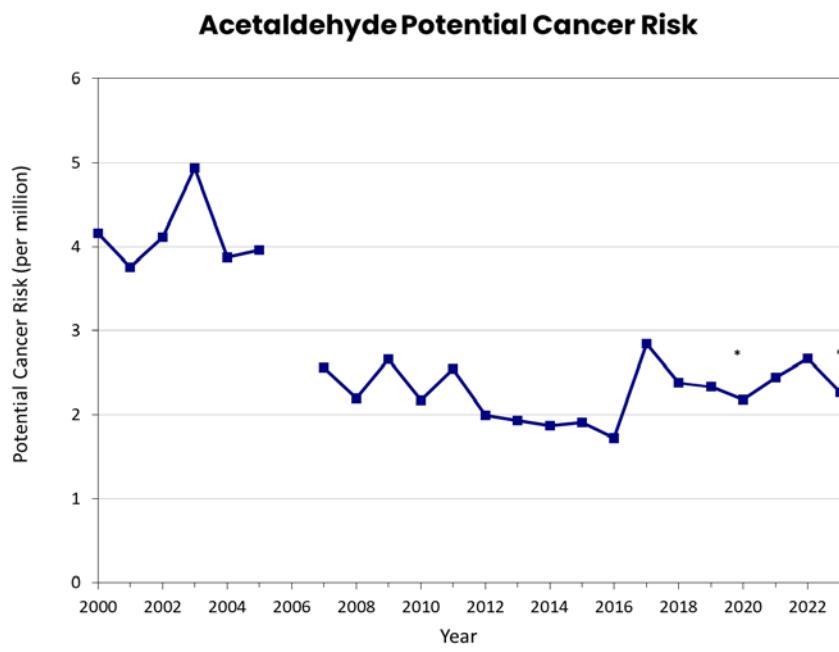

³³EPA Hazard Summary; <https://www.epa.gov/sites/production/files/2016-09/documents/arsenic-compounds.pdf>.

Acetaldehyde

The EPA lists acetaldehyde as a probable human carcinogen. Acetaldehyde inhalation is also associated with irritation of eyes, throat and lungs, and long-term effects similar to those of alcoholism.³⁴ Main sources of acetaldehyde include wood burning and car/truck exhaust. Acetaldehyde's 2023 average potential cancer risk estimate at Beacon Hill was 2.3 in one million. The 2023 average is only from samples from 1/1/2023 - 6/23/2023 due to all samples after 6/23/2023 being invalidated.

Agency efforts that target vehicle exhaust and wood stove emission reductions also reduce acetaldehyde emissions. Since 2000, we have found a statistically significant drop in risk from acetaldehyde at an average rate of about 0.09 per million per year. However, recent years have shown a slight increase.

Figure 31: Acetaldehyde Annual Average Potential Cancer Risk at Beacon Hill, 2000–2023

* Incomplete dataset in 2020 with only seven months monitoring due to Covid-19. Incomplete dataset in 2023 with only six months of data.

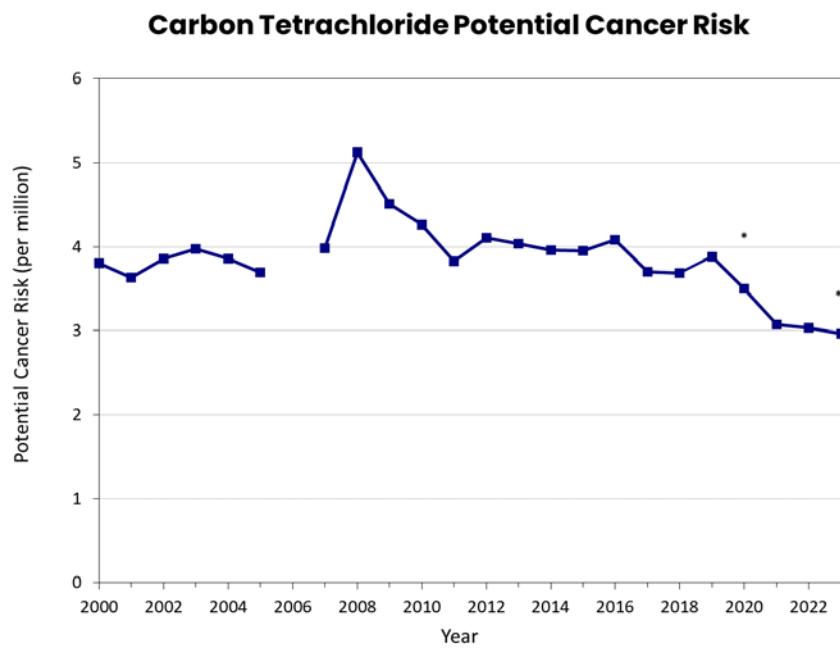

³⁴EPA Hazard Summary; <https://www.epa.gov/sites/production/files/2016-09/documents/acetaldehyde.pdf>.

Carbon Tetrachloride

The EPA lists carbon tetrachloride as a probable human carcinogen. Carbon tetrachloride inhalation is also associated with liver and kidney damage.³⁵ It was widely used as a solvent in both industry and consumer applications and was banned from consumer use in 1995. Trace amounts are still emitted by wastewater treatment plants. Carbon tetrachloride is relatively ubiquitous, has a long half-life, and occurs in similar concentrations in urban and rural areas. Carbon tetrachloride's 2023 average potential cancer risk estimate at Beacon Hill was 3.0 in one million. The 2023 average is only from samples from 1/1/2023 - 6/23/2023 due to all samples after 6/23/2023 being invalidated.

The Agency does not target efforts at reducing carbon tetrachloride emissions, as carbon tetrachloride has already been banned. Since 2000, we have found a statistically significant drop in risk from carbon tetrachloride at an average rate of about 0.03 per million per year.

Figure 32: Carbon Tetrachloride Annual Average Potential Cancer Risk at Beacon Hill, 2000–2023

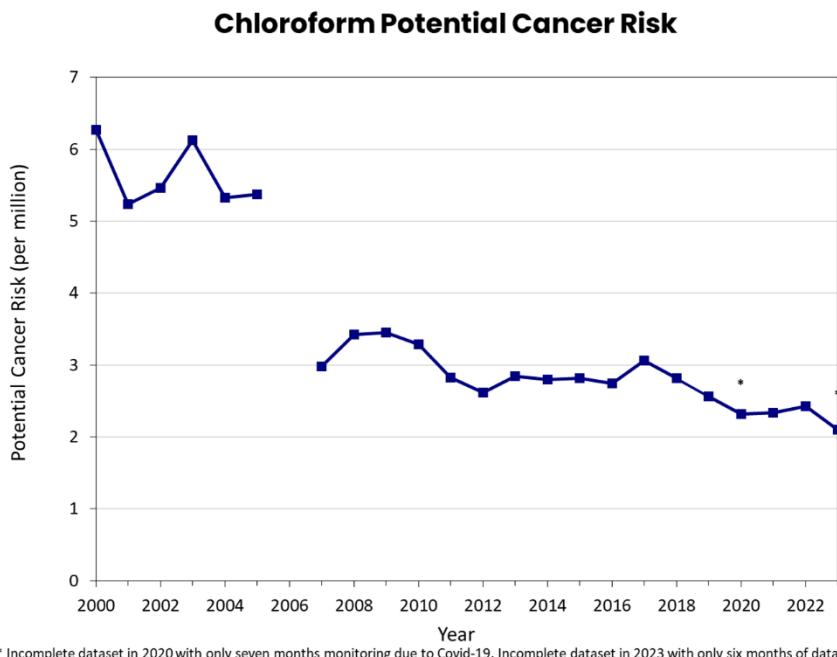

³⁵EPA Hazard Summary; <https://www.epa.gov/sites/production/files/2016-09/documents/carbon-tetrachloride.pdf>.

Chloroform

The EPA lists chloroform as a probable human carcinogen. Chloroform inhalation is associated with central nervous system effects and liver damage.³⁶ Main sources of chloroform are water treatment plants and reservoirs.³⁷ Because the Beacon Hill monitoring site is located at the Beacon Hill reservoir, which was uncovered prior to 2009, the chloroform measurements from 2000 through 2008 may be higher than expected for most of our region. However, the reservoir underwent a major renovation in 2008-09 and is now completely enclosed, possibly at least partially explaining the drop in chloroform levels around that time. Chloroform's 2023 average potential cancer risk estimate at Beacon Hill was 2.1 in one million. The 2023 average is only from samples from 1/1/2023 - 6/23/2023 due to all samples after 6/23/2023 being invalidated.

The Agency does not prioritize efforts to reduce chloroform emissions, as it does not likely present risk in areas other than those directly adjacent to reservoirs, the majority of which have been covered in accordance with a 2006 federal regulation on drinking water protection.³⁸ Since 2000, we have found a statistically significant drop in risk from chloroform at an average rate of about 0.17 per million per year.

Figure 33: Chloroform Annual Average Potential Cancer Risk at Beacon Hill, 2000–2023

³⁶EPA Hazard Summary; <https://www.epa.gov/sites/production/files/2016-09/documents/chloroform.pdf>.

³⁷Seattle Public Utilities. 2018 Water Quality Analysis shows detectable levels of trihalomethanes in treated drinking water, which is stored in reservoirs (trihalomethanes include chloroform, dichlorobromomethane, dibromochloromethane, and bromoform); https://www.seattle.gov/Documents/Departments/SPU/Services/Water/Water_Quality_Report_2018.pdf.

³⁸Long Term 2 Enhanced Surface Water Treatment Rule; <https://www.epa.gov/dwreginfo/long-term-2-enhanced-surface-water-treatment-rule-documents>

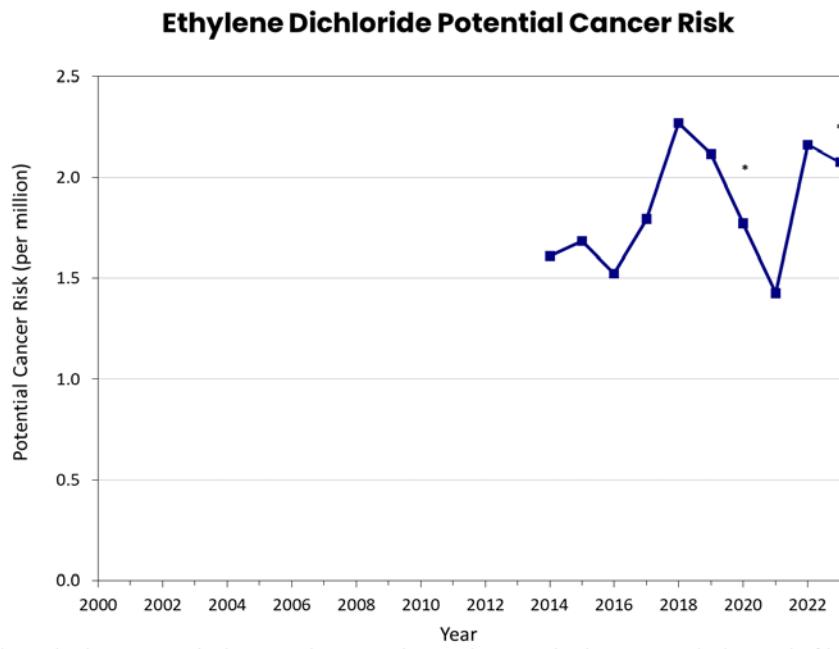

Ethylene Dichloride

EPA lists ethylene dichloride as a probable human carcinogen. It is primarily used as a solvent in the production of other chemicals like vinyl chloride. It is also added to leaded gasoline, but this is expected to be a very minor source, as leaded gas for on-road vehicle use was phased out in 1996.^{39,40} We estimated ethylene dichloride's 2023 average potential cancer risk estimate at Beacon Hill at 2 in one million. The 2023 average is only from samples from 1/1/2023 - 6/23/2023 due to all samples after 6/23/2023 being invalidated.

There is no useful trend information for this air toxic since most of the measurements are near the practical quantitation limit of the analytical method. That is, 93% of the samples in 2023 were within twice the method detection limit. Additionally, in prior years, most of the samples were also below the quantitation limits. In the years for which we have ethylene dichloride data, the detection limit for this air toxic is typically near the one in a million potential cancer risk level.

The Agency's permitting program works with and regulates industrial producers of ethylene dichloride to reduce emissions.

Figure 34: Ethylene Dichloride Annual Average Potential Cancer Risk at Beacon Hill, 2014–2023

³⁹ EPA Hazard Summary, <https://www.epa.gov/sites/production/files/2016-09/documents/ethylene-dichloride.pdf>.

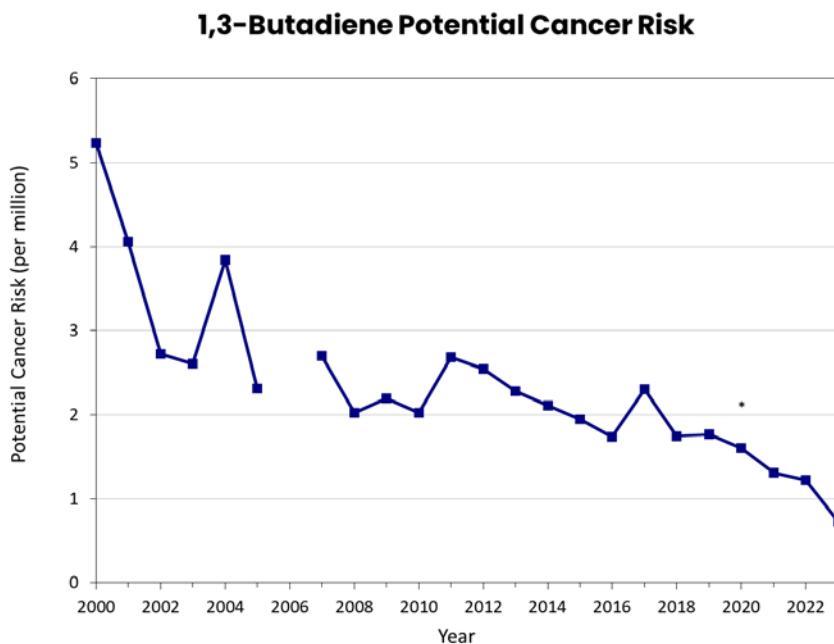

⁴⁰ US Energy Information Administration: Gasoline and the Environment;
https://www.eia.gov/energyexplained/index.php?page=gasoline_environment

1,3-Butadiene

The EPA lists 1,3-butadiene as a known human carcinogen. 1,3-butadiene inhalation is also associated with neurological effects.⁴¹ Primary sources of 1,3-butadiene include cars, trucks, buses, and wood burning. 1,3-butadiene's 2023 average potential cancer risk estimate at Beacon Hill was less than one in one million. The 2023 average is only from samples from 1/1/2023 - 6/23/2023 due to all samples after 6/23/2023 being invalidated. Also, 93% of the samples were below the detection limit, so although we know the values are low, there is some uncertainty on the exact value at such low detection levels.

Agency efforts that target vehicle exhaust and wood stove emission reductions also reduce 1,3-butadiene emissions. Since 2000, we have found a statistically significant drop in risk from 1,3-butadiene at an average rate of about 0.11 per million per year.

Figure 35: 1,3-Butadiene Annual Average Potential Cancer Risk at Beacon Hill, 2000–2023

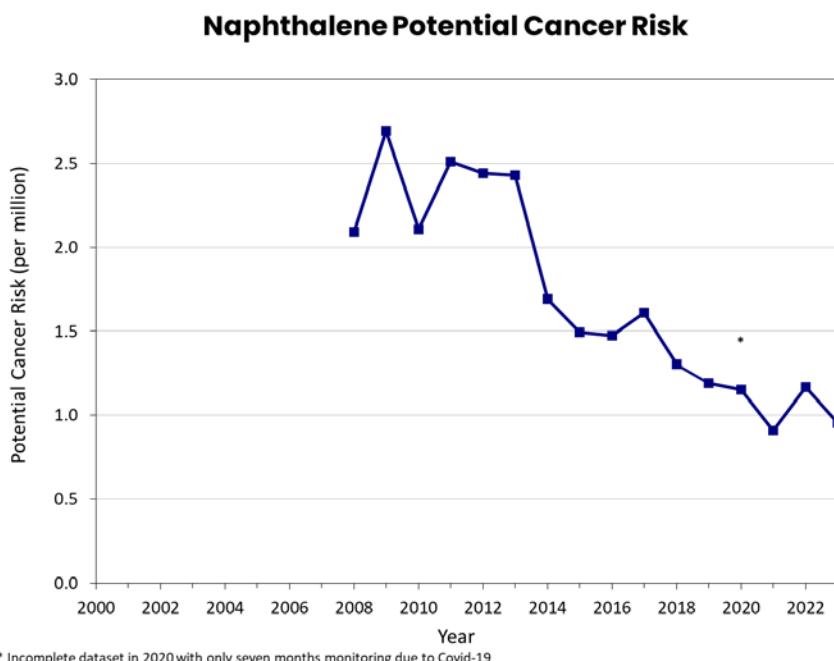

⁴¹EPA Hazard Summary: <https://www.epa.gov/sites/production/files/2016-08/documents/13-butadiene.pdf>.

Naphthalene

EPA lists naphthalene as a possible human carcinogen. Naphthalene is also associated with respiratory effects and retina damage.⁴² Local sources of naphthalene include combustion of wood and heavy fuels. Naphthalene's 2023 average potential cancer risk estimate at Beacon Hill was at 1 in one million.

The Agency works with and regulates wood burning through burn bans and wood stove replacement programs to reduce naphthalene emissions. Since 2014, we have found a statistically significant drop in risk from naphthalene at an average rate of about 0.11 per million per year. Monitoring for naphthalene and other polycyclic aromatic hydrocarbons started in 2008.

Figure 36: Naphthalene Annual Average Potential Cancer Risk at Beacon Hill, 2008–2023

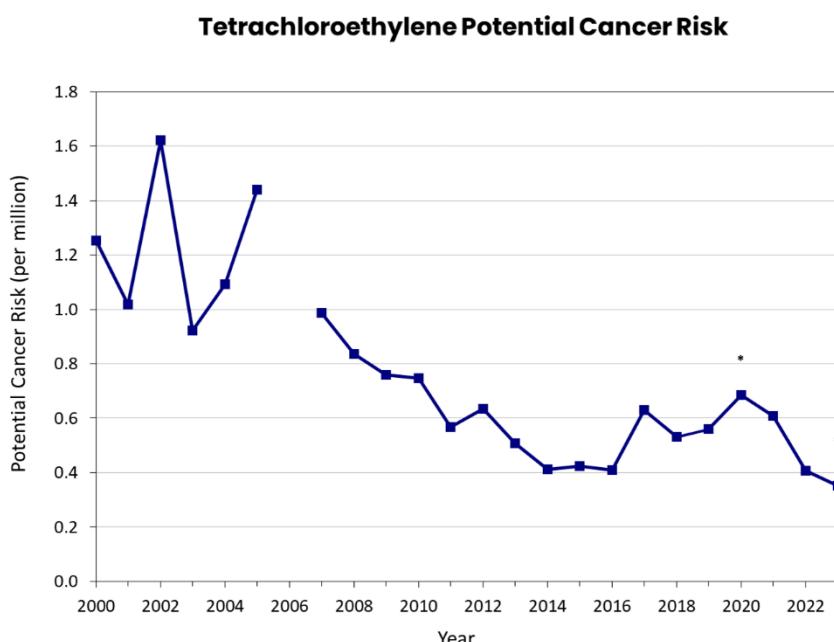

⁴²EPA Hazard Summary; <https://www.epa.gov/sites/production/files/2016-09/documents/naphthalene.pdf>.

Tetrachloroethylene

EPA lists tetrachloroethylene as a probable human carcinogen. It is widely used for dry-cleaning fabrics and textile processing. It is also used for vapor degreasing in metal cleaning process. Chronic exposure to tetrachloroethylene may affect kidney, liver, immune system, and neurological behavior. We estimated tetrachloroethylene's 2023 average potential cancer risk estimate at Beacon Hill was less than one in one million. The 2023 average is only from samples from 1/1/2023 - 6/23/2023 due to all samples after 6/23/2023 being invalidated. Also, 71% of the samples were below the detection limit, so although we know the values are low, there is some uncertainty on the exact value at such low detection levels.

Since 2007, we have found a statistically significant drop in risk from tetrachloroethylene at an average rate of about 0.04 per million per year. The Agency's compliance program works with and regulates dry cleaners and other producers of tetrachloroethylene to reduce emissions.

Figure 37: Tetrachloroethylene Annual Average Potential Cancer Risk at Beacon Hill, 2000–2023

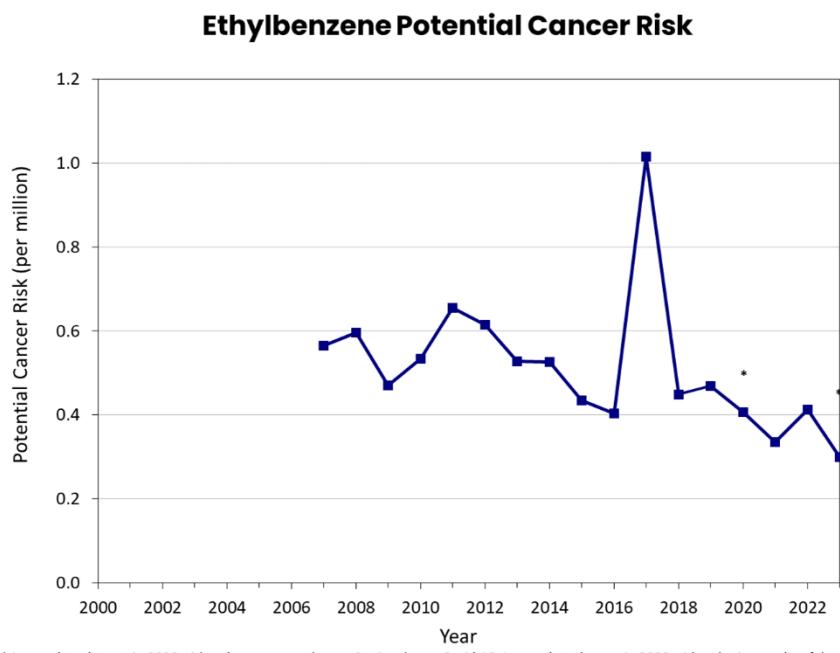

Ethylbenzene

EPA lists ethylbenzene as a Group D pollutant, which is not classifiable as to human carcinogenicity due to limited information available.⁴³ Chronic exposure to ethylbenzene may affect the blood, liver, and kidneys. Local sources of ethylbenzene are from fuels, asphalt, and naphtha. It is also used in styrene production. Ethylbenzene's 2023 average potential cancer risk estimate at Beacon Hill was less than one in one million. The 2023 average is only from samples from 1/1/2023 – 6/23/2023 due to all samples after 6/23/2023 being invalidated.

We did not find a statistically significant trend in ethylbenzene levels over the 2007–2023 timeframe for which we have data. The Agency works with and regulates solvent-using businesses to reduce ethylbenzene emissions.

Figure 38: Ethylbenzene Annual Average Potential Cancer Risk at Beacon Hill, 2007–2023

* Incomplete dataset in 2020 with only seven months monitoring due to Covid-19. Incomplete dataset in 2023 with only six months of data.

⁴³EPA Hazard Summary: <https://www.epa.gov/sites/production/files/2016-09/documents/ethylbenzene.pdf>.

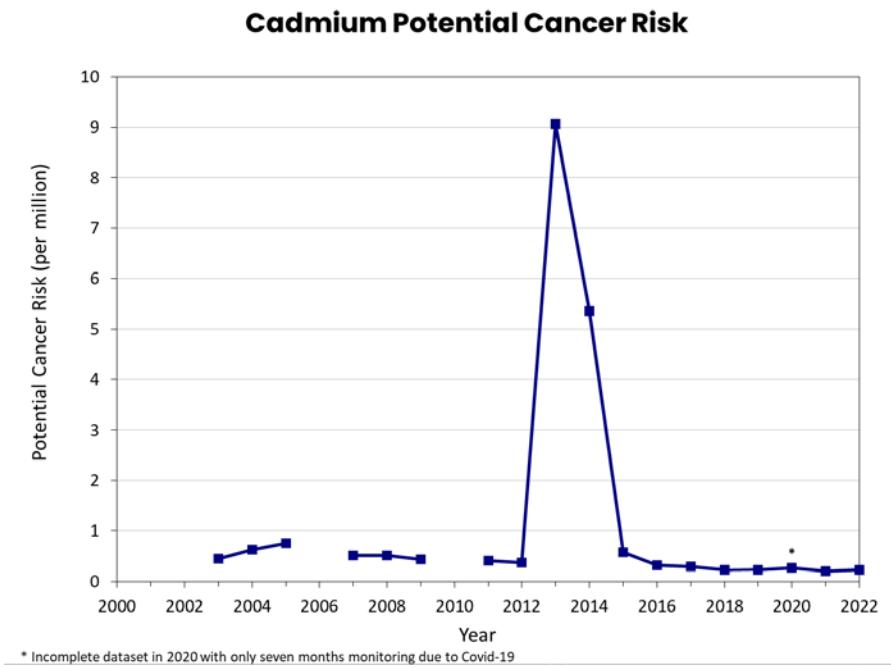

Cadmium (2022)

EPA lists cadmium as a probable human carcinogen. Cadmium exposures are also associated with kidney damage.⁴⁴ Combustion of distillate oil is a main source of cadmium in the Puget Sound area.

Cadmium's 2022 average potential cancer risk estimate at Beacon Hill was less than 1 in one million. Our trend is affected by a number of factors, including the fact that over half the samples in 2010 were below the detection limits and thus we did not have sufficient data to make a comparable average. Extremely high outlier results on 11/18/13 and 9/8/14 resulted in high average concentrations in each of those respective years. On those days, no other metal concentrations were statistical outliers compared to their respective annual variability. With the outliers excluded for 2013 and 2014, the estimated annual potential cancer risks for those years would be < 1. With or without the outliers included, we found no statistically significant trend for cadmium.

The Agency's permitting program works with and regulates industrial producers of cadmium to reduce emissions.

Figure 39: Cadmium Annual Average Potential Cancer Risk at Beacon Hill, 2003-2022

⁴⁴EPA Hazard Summary: <https://www.epa.gov/sites/production/files/2016-09/documents/cadmium-compounds.pdf>.

Air Quality Index

Table 6: 2023 Calculation and Breakpoints for the Air Quality Index (AQI)

Breakpoints for Criteria Pollutants							AQI Categories	
O ₃ (ppm) 8-hour	O ₃ (ppm) 1-hour ^(a)	PM _{2.5} ($\mu\text{g}/\text{m}^3$) 24 hour	PM ₁₀ ($\mu\text{g}/\text{m}^3$) 24 hour	CO (ppm) 8 hour	SO ₂ ^(c) (ppb) 1 hour	NO ₂ (ppb) 1 hour	AQI value	Category
0.000–0.054	—	0.0–12.0	0–54	0.0–4.4	0–35	0–53	0–50	Good
0.055–0.070	—	12.1–35.4	55–154	4.5–9.4	36–75	54–100	51–100	Moderate
0.071–0.085	0.125–0.164	35.5–55.4	155–254	9.5–12.4	76–185	101–360	101–150	Unhealthy for sensitive groups
0.086–0.105	0.165–0.204	55.5–150.4	255–354	12.5–15.4	(186–304) ^(d)	361–649	151–200	Unhealthy
0.106–0.200	0.205–0.404	150.5–250.4	355–424	15.5–30.4	(305–604) ^(d)	650–1249	201–300	Very unhealthy
(b)	0.405–0.504	250.5–350.4	425–504	30.5–40.4	(604–804) ^(d)	1250–1649	301–400	Hazardous
(b)	0.505–0.604	350.5–500.4	505–604	40.5–50.4	(805–1004) ^(d)	1650–2049	401–500	

^(a)Areas are generally required to report the AQI based on 8-hour ozone values. However, there are a small number of areas where an AQI based on 1-hour ozone values would be safer. In these cases, in addition to calculating the 8-hour ozone value, the 1-hour ozone value may be calculated, and the greater of the two values reported.

^(b)8-hour O₃ values do not define higher AQI values (above 300). AQI values above 300 are calculated with 1-hour O₃ concentrations.

^(c)EPA changed the SO₂ standard on June 22, 2010 to be based on an hourly maximum instead of a 24-hour and annual average.

^(d)1-hour SO₂ values do not define higher AQI values (≥ 200). AQI values of 200 or greater are calculated with 24-hour SO₂ concentrations.

For more information on the AQI, see airnow.gov/index.cfm?action=aqibasics.aqi.

Air Shed

A geographic area that shares the same air, due to topography, meteorology and climate.

Air Toxics

Air toxics are broadly defined as over 400 pollutants that the Agency considers potentially harmful to human health and the environment. These pollutants are listed in the Washington Administrative Code at apps.leg.wa.gov/WAC/default.aspx?cite=173-460-150. Hazardous air pollutants (see below) are checked on this list to identify them as a subset of air toxics. Air toxics are also called Toxic Air Contaminants (TAC) under Agency Regulation III.

Criteria Air Pollutant (CAP)

The Clean Air Act of 1970 defined *criteria pollutants* and provided EPA the authority to establish ambient concentration standards for these criteria pollutants to protect public health. EPA periodically revises the original concentration limits and methods of measurement, most recently in 2011. The six criteria air pollutants are: particulate matter (10 micrometers and 2.5

micrometers), ozone, nitrogen dioxide, carbon monoxide, sulfur dioxide and lead. See Appendix page A-21 for more information.

ppm, ppb (parts per million, or parts per billion)

A unit of concentration used for many air pollutants. A ppm (ppb) means one molecule of the pollutant per million (or billion) molecules of air.

Hazardous Air Pollutant (HAP)

A *hazardous air pollutant* is an air contaminant listed in the Federal Clean Air Act, Section 112(b). EPA currently lists 187 pollutants as HAPs at <https://www.epa.gov/haps/initial-list-hazardous-air-pollutants-modifications>.

Temperature Inversions

Air temperature usually decreases with altitude. On a sunny day, air near the surface is warmed and is free to rise. The warm surface air can rise to altitudes of 4,000 feet or more and is dispersed (or mixed) into higher altitudes. In contrast, on clear nights with little wind, the surface can cool rapidly (by 10 degrees or more), which also cools the air just above the surface. The air aloft does not cool, which creates a very stable situation where the warm air aloft effectively caps the cooler air below. This process limits mixing to just a few hundred feet or less. This situation is called a temperature inversion and allows for pollutants to accumulate to high concentrations.

Unit Risk Factor (URF)

A unit risk factor is a measure of a pollutant's cancer risk based on a 70-year inhalation exposure period. The units are risk/concentration. Unit risk factors are multiplied by concentrations to estimate potential cancer risk.

Visibility/Regional Haze

Visibility is often explained in terms of visual range and light extinction. *Visual range* is the maximum distance (usually miles or kilometers) a black object can be seen against the horizon. *Light extinction* is the sum of light scattering and light absorption by fine particles and gases in the atmosphere. The more light extinction, the shorter the visual range. Reduced visibility (or visual range) is caused by weather (clouds, fog, and rain) and air pollution (fine particles and gases).

Volatile Organic Compound (voc)

An organic compound that participates in atmospheric photochemical reactions. This excludes compounds determined by EPA to have negligible photochemical reactivity.

Particulate Matter (PM_{2.5}) - Federal Reference Method

Micrograms per Cubic Meter

Reference Sampling Method: R&P Partisol 2025 Sampler – Teflon Filter

2023

Location	Number of Values	Quarterly Arithmetic Averages				Annual Mean	98 th Percentile	Max Daily Value
		1 st	2 nd	3 rd	4 th			
Seattle Beacon Hill*	81	3.4	4.2	5.7	4.5	4.44	9.6	14.5
Seattle Duwamish	57	6.0	5.4	7.4	7.3	6.51	12.9	19.7

Notes:

- (1) Sampling occurs for a 24-hour period from midnight to midnight.
- (2) Quarterly averages are shown only if 75 percent or more of the data are available. For both sites Q3 sample percentages were below 75%, and for Seattle Beacon Hill Q4 sample percentages were below 75%.
- (3) Annual averages are shown only if there is at least 75 percent of each of the 4 quarterly averages.
- (4) Data from primary sampler at site

* Operated by the Washington State Department of Ecology.

Particulate Matter (PM_{2.5}) – Federal Equivalent Methods

Micrograms per Cubic Meter

Equivalent Sampling Methods: Met One BAM

2023

Estimates of Air Toxics Risk

Potential cancer risk is estimated by multiplying the concentration of a pollutant by its unit risk factor (URF), a constant that takes into account its cancer potency. This is shown in the equation below:

$$\text{Potential cancer risk} = \text{ambient concentration } (\mu\text{g}/\text{m}^3) * \text{unit risk factor } (\text{risk}/\mu\text{g}/\text{m}^3)$$

Unit risk factors are often based on epidemiological studies (studies of diseases occurring in human populations) and are also extrapolated from laboratory animal studies. Unit risk factors are typically based on an assumed 70-year (lifetime) exposure interval and are available from multiple sources. In this data summary, cancer risk was estimated using unit risk factors from the Washington State Acceptable Source Impact Levels (ASIL) table.¹ The ASIL values relevant to this summary are in the table below. The two sources from which values in the ASIL table are derived are the U.S. EPA's Integrated Risk Information System² (IRIS) and California EPA's Office of Environmental Health and Hazard Assessment³ (OEHHA). Unit risk factors from both of these sources are derived from extensive reviews of peer-reviewed literature and other datasets. The cancer rating, based on IARC definitions, refers to its "weight of evidence" ranking: 1 = carcinogenic to humans, 2A = probably carcinogenic to humans, 2B = possibly carcinogenic to humans, and 3 = not classifiable as to its carcinogenicity to humans.⁴

2023 Air Toxics Unit Risk Factors

AIR TOXIC	WA ASIL 460 UNIT RISK FACTOR RISK/ $\mu\text{g}/\text{m}^3$	CANCER RATING ⁵
1,3-Butadiene	3.0×10^{-5}	1

^aPM₁₀ and PM_{2.5} metals data for 2023 not available at the time of this Report. This value is from 2022.

Reference concentrations are based on chronic Reference Exposure Levels (chRELs) from the California Office of Environmental Health Hazard Assessment (OEHHA)⁶.

Mean hazard index, HI = mean concentration/reference concentration.

Acrolein is the only air toxic that fails the screen with a hazard index greater than 1.

⁶ <https://oehha.ca.gov/air/general-info/oehha-acute-8-hour-and-chronic-reference-exposure-level-rel-summary>

2000-2023 Air Toxics Trends Statistical Summary

The following table includes the statistical information for the potential cancer risk trends found in the data summary, including if the trend is statistically significant at the 95% confidence level.

Air Toxic	Significance (p-value)	Slope (change in risk per million per year)	y-intercept	Correlation (R ²)	Number of years (N)
1,3-Butadiene	True (0)	-0.114	3.786	0.691	23
Acetaldehyde	True (0)	-0.091	3.914	0.513	23
Acrolein	False (0.611)	0.030	0.720	0.096	5
Arsenic PM ₁₀ ^a	True (0.003)	-0.050	3.022	0.405	19
Benzene	True (0)	-0.333	10.147	0.718	23
Cadmium PM ₁₀ ^a	False (0.892)	-0.013	1.343	0.001	18
Carbon Tetrachloride	True (0.028)	-0.030	4.227	0.209	23
Chloroform	True (0)	-0.165	5.637	0.782	23
Dichloromethane	False (0.270)	0.001	0.011	0.080	17
Ethylbenzene	False (0.110)	-0.013	0.718	0.161	17
Ethylene Dichloride	False (0.221)	0.041	1.041	0.180	10
Ethylene Oxide	False (0.120)	207	-3613	0.608	5
Formaldehyde	False (0.053)	-0.244	10.108	0.167	23
Naphthalene	True (0)	-0.113	3.570	0.816	16
Nickel PM ₁₀ ^a	True (0)	-0.030	0.857	0.723	18
Tetrachloroethylene	True (0)	-0.039	1.259	0.668	23

^a Trend through 2022. PM₁₀ metals data for 2023 not available at the time of this report.

Air Quality Standards and Health Goals

Pollutant [links to historical tables of NAAQS reviews]	Primary/ Secondary	Averaging Time	Level	Form
Carbon Monoxide (CO)	primary	8 hours	9 ppm	Not to be exceeded more than once per year
		1 hour	35 ppm	
Lead (Pb)	primary and secondary	Rolling 3 month average	0.15 $\mu\text{g}/\text{m}^3$ ⁽¹⁾	Not to be exceeded
Nitrogen Dioxide (NO₂)	primary	1 hour	100 ppb	98th percentile of 1-hour daily maximum concentrations, averaged over 3 years
	primary and secondary	1 year	53 ppb ⁽²⁾	Annual Mean
Ozone (O₃)	primary and secondary	8 hours	0.070 ppm ⁽³⁾	Annual fourth-highest daily maximum 8-hour concentration, averaged over 3 years
Particle Pollution (PM)	PM _{2.5}	primary	1 year	12.0 $\mu\text{g}/\text{m}^3$ annual mean, averaged over 3 years
		secondary	1 year	15.0 $\mu\text{g}/\text{m}^3$ annual mean, averaged over 3 years
		primary and secondary	24 hours	35 $\mu\text{g}/\text{m}^3$ 98th percentile, averaged over 3 years
	PM ₁₀	primary and secondary	24 hours	150 $\mu\text{g}/\text{m}^3$ Not to be exceeded more than once per year on average over 3 years
Sulfur Dioxide (SO₂)	primary	1 hour	75 ppb ⁽⁴⁾	99th percentile of 1-hour daily maximum concentrations, averaged over 3 years
	secondary	3 hours	0.5 ppm	Not to be exceeded more than once per year

(1) In areas designated nonattainment for the Pb standards prior to the promulgation of the current (2008) standards, and for which implementation plans to attain or maintain the current (2008) standards have not been submitted and approved, the previous standards (1.5 $\mu\text{g}/\text{m}^3$ as a calendar quarter average) also remain in effect.

(2) The level of the annual NO₂ standard is 0.053 ppm. It is shown here in terms of ppb for the purposes of clearer comparison to the 1-hour standard level.

(3) Final rule signed October 1, 2015, and effective December 28, 2015. The previous (2008) O₃ standards additionally remain in effect in some areas. Revocation of the previous (2008) O₃ standards and transitioning to the current (2015) standards will be addressed in the implementation rule for the current standards.

(4) The previous SO₂ standards (0.14 ppm 24-hour and 0.03 ppm annual) will additionally remain in effect in certain areas: (1) any area for which it is not yet 1 year since the effective date of designation under the current (2010) standards, and (2) any area for which an implementation plan providing for attainment of the current (2010) standard has not been submitted and approved and which is designated nonattainment under the previous SO₂ standards or is not meeting the requirements of a SIP call under the previous SO₂ standards (40 CFR 50.4(3)). A SIP call is an EPA action requiring a state to resubmit all or part of its State Implementation Plan to demonstrate attainment of the required NAAQS.

National Ambient Air Quality Standards (NAAQS)

The [Clean Air Act](#), which was last amended in 1990, requires EPA to set [National Ambient Air Quality Standards](#) (40 CFR part 50) for pollutants considered harmful to public health and the environment. The Clean Air Act identifies two types of national ambient air quality standards. **Primary standards** provide public health protection, including protecting the health of "sensitive" populations such as asthmatics, children, and the elderly. **Secondary standards** provide public welfare protection, including protection against decreased visibility and damage to animals, crops, vegetation, and buildings.

EPA has set National Ambient Air Quality Standards for six principal pollutants, called "criteria" pollutants (listed below). Units of measure for the standards are parts per million (ppm) by volume, parts per billion (ppb) by volume, and micrograms per cubic meter of air ($\mu\text{g}/\text{m}^3$).

EPA is required to re-visit and update standards every five years, to incorporate the latest health and welfare information.

The state of Washington and the Puget Sound region have adopted these standards. For more information, EPA air quality standards and supporting rationale are available at <https://www.epa.gov/criteria-air-pollutants>. Washington State air quality regulations are available at <https://ecology.wa.gov/Regulations-Permits?topics=27>.⁷ The air quality standards that apply to the Puget Sound air shed are summarized below.

Pollutants typically have multiple standards with different averaging times; for example, daily and annual standards. Multiple standards are created and enforced to address health impacts as a result of a shorter, high-level exposure versus longer, low-level exposures. These differences are addressed pollutant-by-pollutant. Additional information is on EPA's website at <https://www.epa.gov/criteria-air-pollutants/naaqs-table>

The Agency has developed an air quality health goal for daily PM_{2.5} concentrations. The Agency convened a Particulate Matter Health Committee, comprised of local health professionals, who examined the fine particulate health research.⁸ The Health Committee did not consider the federal standard at the time to be protective of human health. In 1999, the Agency adopted a health goal of 25 $\mu\text{g}/\text{m}^3$ for a daily average, more protective than the current federal standard of 35 $\mu\text{g}/\text{m}^3$. This level is consistent with the American Lung Association's goal and the EPA Clean Air Science Advisory Committee's recommended lower range for the EPA's 2006 ambient air quality standard revision.⁹ The Agency did not adopt a separate health goal for the annual average.

⁷Washington Administrative Code chapters 173-470, 173-474, and 173-475.
